Stephen Victor Balderston, Evanston, Ill., University of Pennsylvania Department of Medicine, Philadelphia, 1895, associate in medicine at the Northwestern University Medical School, Chicago, specialist certified by the American Board of Internal Medicine, served in the medical corps of the U. S. Army during World War I, health commissioner of Evanston from 1907 to 1914, for many years on the staff of the Evanston Hospital, aged 74, died, July 11, of coronary occlusion.

Mack W. Ball, New Bern, N. C., Atlanta (Ga.) School of Medicine, 1909, aged 75, died, July 6, in the Duke Hospital, Durham, of angina pectoris.

Sydney Elon Bateman, Mifflinburg, Pa., Medico-Chirurgical College of Philadelphia, 1904, formerly a Lutheran minister, served as a major in the medical corps of the U. S. Army during World War I, aged 79, formerly adjunct professor of histology and embryology at the Temple University School of Medicine, Philadelphia, died, July 7, in the Geisinger Memorial Hospital, Danville, of acute cholelithiasis, uremia and coronary occlusion.

Everett Charles Beach, Oxnard, Calif., Baltimore Medical College, 1907, member of the California Medical Association, formerly supervisor of physical education in the city schools of Los Angeles and at one time director of physical education in the summer school at the University of California, Berkeley, on the staff of St. John's Hospital, aged 63, died, July 8, in the California Hospital, Los Angeles, of brain tumor.

Harold Kohli Begg, Cleveland, Northwestern University Medical School, Chicago, 1918, for many years physician for the Rams and Barons, professional football and hockey teams, aged 48, died, July 13, in the Huron Road Hospital of virus pneumonia following a thyroid operation.

Theodore S. Blakesley, Kansas City, Mo., Rush Medical College, Chicago, 1902, specialist certified by the American Board of Otolaryngology, member of the American Academy of Ophthalmology and Otolaryngology, served during World War I, member of the staffs of the Trinity Lutheran, St. Luke's, St. Joseph, Research and the Kansas City General hospitals, aged 65, died, July 14, in Columbus, Ohio, of coronary occlusion.

Charles James Carden, Tewksbury, Mass., Harvard Medical School, Boston, 1896, member of the Massachusetts Medical Society, served as a major in the medical corps of the U. S. Army during World War I, formerly on the staff of the Tewksbury State Hospital and Infirmary as assistant physician, aged 70, died, July 4, of arteriosclerotic heart disease, lobar pneumonia and diabetes mellitus.

Douglas Aymar Cater, East Orange, N. J., Columbia University College of Physicians and Surgeons, New York, 1896, fellow of the American College of Surgeons, consulting physical therapist and formerly senior member of the staff of the Orange Memorial Hospital, aged 73, died, July 13, of coronary thrombosis and arteriosclerosis.

Andrew D. Clark, Adrian, Mich., Illinois Medical College, Chicago, 1910, aged 70, died, July 2, of heart disease.

R. Garn Clark, Provo, Utah, College of Physicians and Surgeons, Baltimore, 1904, member of the Utah State Medical Association, served for two years as mayor of Richfield, at one time medical director of the Richfield General Hospital, aged 66, died, July 8, in the Utah Valley Hospital of coronary occlusion.

John Hamilton Cooper, Massillon, Ohio, University of Pittsburgh School of Medicine, 1913, also a pharmacist, member of the American Academy of Ophthalmology and Otolaryngology, specialist certified by the American Board of Otolaryngology, on the staff of the Massillon State Hospital, aged 61, died, July 15.

Isham E. Cottingham, Evansville, Ind., University of Louisville (Ky.) Medical Department, 1879, Bellevue Hospital Medical College, New York, 1881, member of the Indiana State Medical Association, aged 85, died in the Welborn Walker Hospital, July 9, of heart disease.

William Edward Cramm, Mansfield Center, Conn., University of Vermont College of Medicine, Burlington, 1895, served in the medical corps of the U. S. Army during World War I and as a captain in the medical reserve corps not on active duty, health officer of Mansfield for many years, a member of the visiting staff of the Windham Community Memorial Hospital, Willimantic, one of the founders and first president of the Mansfield Center Library, aged 73, died, July 7, of generalized abdominal carcinoma.

James Edward Daley, Porterville, Calif., California Medical College, San Francisco, 1895, aged 72, died, July 3, in a San Francisco hospital of paralysis of the throat and auricular fibrillation.

Edgar Childes Dawson, Niles, Calif., University of California Medical School, San Francisco, 1932, served on the staff of the Alameda Hospital, aged 35, died at Mount Eden, July 7, of multiple sclerosis.

Thomas J. Draper, Warrensburg, Mo., University Medical College of Kansas City, Mo., 1894, served as public health officer of Johnson County, aged 87, formerly on the staff of the Warrensburg Clinic, where he died, July 6, of an infection of the bladder.

Austin Ray Edwards, Sidney, Ohio, Ohio State University College of Medicine, Columbus, 1916, member of the Ohio State Medical Association, served overseas during World War I, formerly coroner, on the staff of the Wilson Memorial Hospital, aged 55, died, July 10, of congestive heart disease.

Roland A. Felt, Virginia, Ill., Barnes Medical College, St. Louis, 1899 and 1909, member of the Illinois State Medical Society, served in the medical corps of the U. S. Army during World War I, on the staffs of the Passavant Memorial and Our Saviour's hospitals, Jacksonville, aged 66, died, July 9, in St. John's Hospital, Springfield, of right pyelonephritis and urinary sepsis.

James Hudson Fiscus, Greensburg, Pa., University of Maryland School of Medicine, Baltimore, 1910, served as a captain in the medical corps of the British army during World War I, dermatologist on the staff of the Westmoreland Hospital, aged 58, died, July 4, of acute myocarditis.

Edward James Fitzgibbon, Boston, Harvard Medical School, Boston, 1904, formerly associated with the U. S. Veterans Bureau, aged 79, died in the United States Naval Hospital, Chelsea, Mass., July 12.

Tilden P. Fowler, Harrison, Ark. (licensed in Ark. in 1903), member of the Arkansas Medical Society, aged 61, died, July 4, of cerebral hemorrhage.

Louis Morris Green, Maywood, Ill., University of Illinois College of Medicine, Chicago, 1912, examining physician for the Baltimore and Ohio Railroad, served during World War I.

I aged 62 died in the Veterans Administration Facility Downer July 18 of chronic myocarditis myocardial degeneration and cerebral arteriosclerosis

Theodore Laurence Gregg Lewisburg, Ohio Eclectic Medical Institute Cincinnati 1897, aged 68, died July 21, in Los Angeles of cerebral hemorrhage

Edward William Grosser, Chicago Chicago Homeopathic Medical College, 1901 Rush Medical College Chicago, 1902, the Hahnemann Medical College and Hospital Chicago 1905, aged 69 died, July 24 of chronic myocarditis and operation for carcinoma of the left kidney

Benjamin Franklin Gumbiner, Gary Ind., Rush Medical College Chicago 1920 member of the Indiana State Medical Association aged 47, on the staffs of St Mary's Mercy and Methodist Hospital where he died July 17 of pulmonary edema

Charles Joseph Hart & New York University and Bellevue Hospital Medical College New York 1921, director of the x-ray department of the Wickersham Hospital, aged 43, died in the Rutland (Vt) Hospital July 13 of acute dilatation of the heart following radical sinus operation

Emil Frank Hartung, Rockville Centre N Y, Long Island College Hospital Brooklyn 1884 at one time coroners physician in Brooklyn member of the draft exemption board during World War I formerly on the staff of the Trinity Hospital Brooklyn aged 81 died July 17 of senility

Stanley Morton King & Brooklyn Albany Medical College 1915 specialist certified by the American Board of Otolaryngology served as a captain in the medical corps of the U S Army during World War I aged 52 a member of the staffs of the New York Eye and Ear Infirmary New York and the Methodist Hospital where he died July 27 of carcinoma of the kidney

Alfred Coleman Kinney & Seaview, Wash Bellevue Hospital Medical College, New York 1872 an Affiliate Fellow of the American Medical Association member, the founder and the first and fiftieth president of the Oregon State Medical Society one of the first members of the Oregon State Board of Health mayor of Astoria Ore. from 1894 to 1896 in 1938 received the honorary degree of doctor of laws from the Linfield College McMinnville, Ore., aged 93 died, July 13 in St Vincent's Hospital Portland Ore

Frank Ambrose Lagorio, Chicago Northwestern University Medical School Chicago 1911 member of the Illinois State Medical Society for many years chief physician of the Illinois Athletic Commission a member of the board of the Chicago Public Library and head of the Chicago Pasteur Institute on the staffs of the Columbus and Cuneo hospitals aged 58 died suddenly in Winnetka, Ill July 18 of coronary thrombosis

Nathan Lane Brooklyn Columbia University College of Physicians and Surgeons New York, 1902 member of the Medical Society of the State of New York aged 58 died in the Harkness Pavilion of the Presbyterian Hospital New York July 18 of chordoma.

Robert Leroy Leighton & Spring Lake, N J Hahnemann Medical College and Hospital of Philadelphia 1913 served overseas as a captain in the medical corps of the U S Army during World War I member of the borough council of Spring Lake on the staff and member of the board of governors of the Fitkin Memorial Hospital, Neptune aged 53 died July 5 of bronchogenic carcinoma

Charles P Leuthart, New Albany, Ind Kentucky School of Medicine Louisville 1901 member of the Indiana State Medical Association for many years secretary of the Floyd County Board of Health aged 70 died July 16 of prostatism and myocarditis

Gustav Edward Liebrecht, Chicago National Medical University Chicago 1906 veteran of the Spanish-American War, on the staff of the Lutheran Deaconess Home and Hospital, aged 72 died July 26 of chronic myocarditis

Frank Ford McDede & Paterson N J College of Physicians and Surgeons Baltimore 1901 served as a captain in

the medical corps of the U S Army during World War I, examining physician for the Selective Service System, aged 75, on the staff of St Joseph Hospital, where he died, July 9, of intestinal obstruction

Stanley Willis Osgood, Clawson, Mich., Detroit College of Medicine and Surgery, 1931, member of the Michigan State Medical Society, commissioned as a captain in the medical corps Army of the United States, in September 1942 and relieved from active duty on account of physical disability in March 1943 served on the staffs of Mount Carmel Mercy Hospital, Detroit, and St Joseph Mercy Hospital Pontiac, aged 37 died, July 21, of carcinoma of the thyroid

John Breckenridge Overall, Springfield, Ky., Louisville Medical College, 1892, member of the Kentucky State Medical Association, served during World War I, major in the medical reserve corps not on active duty, mayor of Springfield, charter member of the Rotary Club and a member of the board of directors of the Springfield State Bank, aged 74, died, July 1, of cerebral hemorrhage

William Gerard Paradis & Crookston, Minn., University of Minnesota Medical School, Minneapolis, 1926, past president of the Minnesota Sanatorium Association and the Red River Valley Medical Society, fellow of the American College of Chest Physicians member of the staffs of St Vincent's and Bethesda hospitals, medical director and superintendent of the Sunny Rest Sanatorium, where he died, July 7 of coronary thrombosis

Thomas Francis Patterson, Brooklyn Long Island College Hospital, Brooklyn 1896 member of the Medical Society of the State of New York aged 71 died, July 24

Benjamin William Peck, Burnsville, W Va Maryland Medical College Baltimore 1905 aged 69 died July 8 of nephritis

William Peters, Nicasio Calif., College of Physicians and Surgeons of San Francisco 1900 formerly on the staff of the Franklin Hospital San Francisco, aged 69 died, July 2 of heart block.

Samuel Benjamin Pond, Patton, Calif University of Minnesota College of Homeopathic Medicine and Surgery, Minneapolis 1907 member of the California Medical Association and the American Psychiatric Association on the staff of the Patton State Hospital formerly on the staff of the Middletown (N Y) State Homeopathic Hospital, aged 60 died in St Bernardine's Hospital San Bernardino, July 20 of cerebral embolus following a prostatectomy

Dallas Case Ragland, Los Angeles, Washington University School of Medicine St Louis 1907 formerly professor of pathology and hygiene at the College of Physicians and Surgeons aged 58, died July 10 of cerebral hemorrhage.

Charles Henry Reinhardt, Chicago, University of Illinois College of Medicine Chicago 1915 served during World War I aged 51 died July 25 in the Wesley Memorial Hospital of carcinoma of the lung

Hugo August John Siebeneichen, New York University and Bellevue Hospital Medical College, New York 1916 for many years diagnostician for the department of health aged 49 died July 22 of coronary occlusion

James F Waltz & Capac Mich Detroit College of Medicine 1907 served during World War I president of the village of Capac 1931-1932 on the staffs of the Bishop Hospital Almont Harper Hospital Detroit, and Port Huron (Mich) Hospital aged 57 died June 24 of coronary occlusion

KILLED IN ACTION

Walter Wytowich Detroit Wayne University College of Medicine, Detroit, 1941 served on the staff of the Grace Hospital commissioned a first lieutenant in the medical corps of the Army of the United States in March 1942, received the Purple Heart aged 27 was killed in action in the North African area July 11

LIEUT WALTER WYTOWICH
1916-1943

Vitagen—College International Inc., Denver Shipped April 22 1941 Composition approximately 70 per cent deficient in vitamin A and 50 per cent deficient in vitamin C, from figures claimed on label Adulterated because valuable constituents namely vitamins A and C had been wholly or partly omitted or abstracted therefrom Misbranded because statements, "two tea spoons of Vitagen contains approximately 2810 international units of A 450 units of C were false and misleading when applied to an article of lower vitamin content"—[D D N J F D C 630 February 1943]

West Point Hair Tonic—Associated Brands Inc Brooklyn Shipped Jan 22 1941 Composition essentially alcohol water castor oil benzyl benzoate and benzoic acid Misbranded because of false and misleading statements (on carton) "Natural Vegetable Oil Hair Tonic" and "West Point Hair Tonic wakes up tight lazy curls and brings new life to hair" For Thinning Hair Teach the children to use West Point Hair Tonic. It will insure their having healthy beautiful hair when they grow older, and (on label) "Natural Vegetable Oil Hair Tonic."—[D D N J F D C 585 Noember 1942]

Zalco Septic—Sylvia Zalk trading as Zalco Company St Paul Shipped between Feb 1 and Sept 25 1940 Composition essentially water alcohol and small amounts of menthol eucalyptol thymol methyl salicylate and boric acid Misbranded because when used in the dilutions recommended it was not an antiseptic for feminine hygiene.—[D D N J F D C 630 February 1943]

SOME MISCELLANEOUS MEDICAL FRAUDS

A Variety of Schemes Debarred from the Mails

Fraud orders issued by the Post Office Department have frequently been the subject of extensive articles by the Bureau of Investigation in these pages of THE JOURNAL. Following are brief abstracts of some fraud orders not dealt with previously.

E J Stevens New Age Book and Supply House and New Age Company—in this department of THE JOURNAL, Nov 8 1941, page 1642 there was reviewed the record up to that date of Ernest J Stevens of San Francisco including a Post Office fraud order issued May 17 1941, against a long list of trade styles under which Stevens had operated. Among these were Stevens Helio-Scientific Company The Rainbow Publishing Company E. J Stevens Publishing Company and The E J Stevens Color Institute. The article concluded with this paragraph:

As in many similar cases the flaw in this fraud order lay in the omission of Stevens personal name and so like some others whose schemes have been debarred from the mails he flouted the government and continued in business—by operating under a new trade style and local address Chromolux Company Stratford Hotel San Francisco His device also took on a new name Chromolux Lamp His explanation to those on his mailing list was that his companies had been reorganized. But this trick was soon detected by the Post Office Department which on July 12 1941 issued a supplemental fraud order covering not only the name of Stevens himself but also the Chromolux Company Lux Stevens and a good many other trade styles old and new under which he had been operating. But Stevens is not the kind of person to let a few fraud orders or other government ukases stand in the way or his financial success and so he simply dropped his old trade styles and adopted fresh ones namely New Age Company and New Age Book and Supply House, and the business of promoting his normalizer went merrily on for a while. With it was advertised a manual entitled True Chromo Therapy which was represented to contain color-energy treatments for scores of diseases. This was reported by the Post Office Department to be the same manual which was involved in the earlier case against Stevens when it was found to contain false and fraudulent claims for the treatment of disease by the Stevens devices. When it became evident to the Post Office Department that the trade styles New Age Book and Supply House New Age Company and E J Stevens MSc. PhD were names under which Stevens was continuing to promote his scheme a supplemental fraud order was issued against these titles on Feb 15 1943.

Holder's H F Condensator Company Holder's Research Laboratories W E Holder MD Dr D O Crowe DMT and others—These concerns and persons whose addresses were given variously as Detroit and Windsor Ontario Canada promoted through the mails a device called at different times Holder's H F Condensator Holder's Ultra Short Wave Condensator and Holder's Ultra Short Wave H F Condensator. The moving spirit in the scheme was a William E. Holder who formerly had advertised and sold through the mails a rubber chair cushion containing an electrical heating unit represented as a curative agency for a large number of serious diseases and other ailments. The operation of that scheme through the mails resulted in the issuance of a Post Office fraud order on Dec. 23 1938 which closed the mails to Holder and others as reported in this department of THE JOURNAL, Sept. 9 1939 page 1051. Thereafter it appears Holder deemed Canada a more propitious place for his activities and set up his new enterprise in Windsor later opening an agency in Detroit which was run by D O Crowe. Holder promoted his condensator in certain publications circulating through the mails. In one advertisement he addressed his message to so-called incurables suffering from asthma bronchitis sinusitis

hay fever colds mastoid and throat troubles arthritis and all rheumatic conditions paralysis spinal troubles neurasthenia stomach disorders prostate kidney and bladder trouble women's weaknesses eye ailments including cataract and glaucoma etc. who have endeavored in vain to obtain relief. Getting down to business his advertisement went on to say: "Such sufferers need not despair for that internationally known miracle machine Holder's Ultra Short Wave H F Condensator (not diathermy) generating fluid electricity with cellular massage is now being manufactured in Detroit so that United States physicians can give this wonderful treatment to aid sufferers in their recovery to good health."

Endorsed by the British Ministry of Labor and advertised by the British Ministry of Health as the successful treatment for colds hay fever and sinus trouble. Inquirers received a printed form letter together with various so-called physicians case history reports a 32 page booklet on the condensator and other material. The booklet contained such claims as: "All bacteria free illnesses are simply electrical unbalance. All drugs used for curative purposes must ultimately depend upon their electrical qualifications. Pain is the result of electric unbalance. Knowing these features I came to the conclusion that to balance the electrical potential in the human body it would be necessary to produce a machine which would embody the essential features necessary."

The booklet went on to explain that these features were: (1) To produce a current with immense oscillations (2) A current which would be germicidal and have nutritional value. (3) A current of extremely high voltage (4) A current of very low amperage. (5) A current with open circuit or spark gap to produce a damped field or electronic condensation (This cannot be done otherwise). Also in the booklet was the promoter's claim that the ultra short wave current which is generated in my condensator now is of a 3 meters wave length or 100 000 000 oscillations per second 50 000 volts intake, 2 amps or 200 milliamperes. Further there were numerous testimonials and statements alleged to have come from physicians reporting the supposed cures of a wide variety of disorders such as blood poisoning paresis infantile paralysis cancer, including inoperable stomach cancer liver tumor epilepsy diabetes pyorrhea black widow spider bite varicose veins cirrhosis of the liver exophthalmic goiter mental diseases obesity impotence high blood pressure and many others. The only condition which the literature admitted Holder's Therapy would not remedy was abnormality of spine—whatever that may be. The device sold for \$365 and though Holder contended that it was distributed only to physicians the Post Office inspector declared that test cases that he had conducted had shown that anyone who would send the required amount would be supplied with a condensator. On Aug 24 1942 the Post Office Department directed the persons and concerns in question to show cause on September 21 of that year why a fraud order should not be issued against them. At the hearing which had been postponed to October 7 an attorney appeared for the respondents. There was produced in evidence a specimen of Holder's device and examination showed that it consisted of a wooden cabinet about 15 inches high, about 17 inches wide and approximately 12 inches in depth. At the bottom of the cabinet was a wooden drawer in which various glass electrodes and other attachments were found. On a bakelite panel inside the top lid was a switch for turning the device on and off with two control indicators a socket for the insertion of the treatment attachments and a number of quarter inch holes from which ozone emanated when the control indicator was turned to the proper mark. On the right hand side were three holes for the placing of bipolar and electrode attachments. Current was furnished to the device by connecting it with the regular electrical outlet of home or office either alternating or direct current. Though the directions for use called for different modes of treatment for various diseases and conditions a government witness brought out the fact that, in general the therapy was applied locally to the area affected by the disease and elsewhere on the body. In addition to treatment by application of the electrical attachments the ozone emanations were recommended in certain conditions. Dietary instructions were furnished and the use of food cooked in aluminum ware was prohibited. A qualified electrical and radio engineer who had spent many years in examining electrical devices testified for the government that in going over the condensator he had employed the best scientific instruments and followed well recognized testing procedures and that though this device was represented in the advertising to produce 100 000 000 oscillations per second the examination at the National Bureau of Standards showed that it actually produced not more than 250 000 oscillations or kilocycles. A qualified physician specializing in physical therapy testified for the government that the use of the condensator would not cure so-called incurables suffering from any of the numerous disorders listed in the advertising and that even if heat is indicated in the treatment of any of these the amount of heat given off by the condensator would not penetrate deeply enough to produce any significant results. He testified further that one of the diseases in question require surgery x-ray and other types of therapy for their proper treatment. It was brought out also that William E. Holder originator and principal promoter of the device is not a physician had never attended any electrical school and has no scientific or college education of any sort and that in treating persons at his residence in Windsor Ontario he takes at face value their statements about their physical condition that he has had no qualified physicians associated with him was derogated from Chicago to Canada several years ago by the emigration authorities because of his promotion of the electric rubber chair cushion scheme previously mentioned and is present is barred from returning to the United States. He is a British subject born in England in 1892. Because of his false mail order campaign which the government charged was a scheme to defraud the public a fraud order was issued Dec. 22 1942 against E. J. D. O. Crowe and other names under which their operations were conducted.

Correspondence

REMOVAL OF TESTES IN TREATMENT OF MELANOMA

To the Editor—The clinical note "Malignant Melanoma of the Choroid with Extensive Metastasis Treated by Removing Secretory Tissue of the Testicles," by William P. Herbst, published in *The Journal*, June 26, assumes that removal of the testes for melanoma may be followed by temporary clinical improvement as shown by the progress of the case reported following orchiectomy.

The following summary represents an example in which removal of the testes had no clinical effect in delaying the rapid downhill progress in a similar instance of widespread melanoma.

E. W., a white man aged 47, admitted to the clinic of the Brooklyn Cancer Institute on Jan 19, 1942, first noticed a small black spot at the inner angle of his eye eight years before. Up to five years before there was hardly any noticeable increase in its size. In the last year "this black spot" had grown into a fleshy tumor mass.

A coal black papilloma measuring 0.5 by 1 by 1 cm, arising from the conjunctival surface of the lower lid, filled the inner canthus of his left eye. The patient was in good general health without evidence of metastases. His liver was not enlarged.

A radical exenteration of the orbit was recommended. This was done in another institution on Jan 30, 1942. The pathologic diagnosis was melanoma of cornea and conjunctiva. By February 20 most of the skin grafts had taken and the patient was discharged.

For about one year, or until February 1943, he was followed through the clinic of the Brooklyn Cancer Institute without evidence of disease. In February a subcutaneous, button-like node was felt in the anterior abdominal wall. This was excised and shown to be a metastatic melanoma. Soon after, bluish black nodules developed on the roof of the orbit and numerous discrete, subcutaneous metastases were found scattered over most of his body. His liver enlarged rapidly, ascites accumulated. It was at this time that members of the staff of the Brooklyn Cancer Institute decided to remove his testicles with the hope that the removal of the testicular male hormone might in some way impede the rapid growth and spread of these metastatic lesions.

A bilateral orchiectomy was done on April 26. There was no postoperative reaction. The patient, however, showed no evidence of clinical improvement. His downhill course was rapid and he died on June 24, 1943.

An autopsy was obtained. The following is a summary of the anatomicopathologic diagnosis: melanoma arising in conjunctiva of left eye (exenteration left orbit), metastasis of the orbital roof, metastases to skin, both lungs, hilar glands, pleurae, pleural effusion, right, metastases to pericardium, myocardium, metastases to spleen, liver, kidney, mesentery, peritoneum, omentum, ascites. There was nothing in the gross or microscopic study to suggest that the orchiectomy had in any way affected the progress of his disease.

So far the only inferences which link melanoma to the sex glands arise from the following facts:

1 With adolescence there is a localized deposition of pigment in the skin of the genitals and about the areola of the breasts.

2 Pigmented nevi which remain quiescent during infancy and childhood have been known to become activated during adolescence or later in life. The only reported case of a baby dying of malignant melanoma is that of Parkes Weber (Spontaneous Inoculation of Melanotic Sarcoma from Mother to Fetus, *Brit M J* 1 537 [March 22] 1930), who described a case of melanoma transmitted from mother to child via the placenta with death of both.

The brilliant research of Huggins, Stevens and Hodges (Studies on Prostatic Cancer. II The Effects of Castration on Advanced Carcinoma of the Prostate Gland, *Arch Surg* 43 209 [Aug] 1941), which led up to the removal of the testes and the use of diethylstilbestrol in carcinoma of the prostate, and the work of Schinzinger (*Carcinoma Mammæ, Verhandl d deutsch Gesellsch f Chir* 18 28, 1889), and Beatson (On the Treatment of Inoperable Cases of Carcinoma of the Mamma. Suggestions for a New Method of Treatment, with Illustrative Cases, *Lancet* 2 104, 162, 1896), who first demonstrated the efficacy of castration for temporary alleviation of widespread metastases in mammary carcinoma, have no counterpart in any work done on melanoma.

It is therefore suggested that great caution be exercised and a great deal more basic research be done before the testes be removed as a routine measure in the treatment of melanoma.

WILLIAM E. HOWES, M.D., Brooklyn

ELECTROCARDIOGRAPHIC CHANGES IN HEART WOUNDS

To the Editor—In *THE JOURNAL*, July 3, page 664, Dr. Mandel Weinstein reported a case of stab wound of the heart. In the interpretation of the electrocardiograms, he stated "Our patient's records show the typical progression of changes seen in infarction on the anterior wall of the heart." Inspection of the electrocardiograms, however, reveals patterns which are quite typical not of infarction but rather of acute pericarditis, which, of course, is always present in any case in which an operation on the heart is performed. In other reported cases, as in this case, when a coronary artery is not ligated or involved by the wound, the electrocardiographic changes due to the wound are frequently obscured by those of pericarditis. When a coronary artery is injured or ligated, one then sees either a combined pattern of infarction and pericarditis or, occasionally, the pattern of infarction alone. In the latter cases the changes due to pericarditis are masked or neutralized by those due to the infarction. Dr. Arlie R. Barnes and I (*Arch Int Med* 65 291 [Feb] 1940) briefly summarized the literature on the electrocardiographic changes reported in heart wounds and the reader is referred to this article for further details.

The electrocardiogram of pericarditis has been recognized only relatively recently. While it simulates that of myocardial infarction, there are a number of points of difference which enable one to make the correct diagnosis. The importance of this differentiation is obvious.

MEDICOLEGAL ABSTRACTS

Hospital Association Not Exempt from Taxation as Charitable Institution if Charity or Benevolence is Limited to Members—The Farmers Union Hospital Association of Elk City, Okla., was incorporated under the laws of Oklahoma relating to corporations for benevolent and charitable purposes its articles of incorporation specifically providing that it should have no capital stock and that its profits, if any, should not inure to the benefit of the individual members but should be used for charitable and benevolent purposes. The corporation undertook to render medical and hospital care both to members of the corporation and to nonmembers. Members paid a membership fee of \$50 and an annual fee that varied from year to year, being an estimate of the cost of its services for the current year in the light of past experience and future expectations. In return members received necessary hospital and medical services and care. Nonmembers could receive available services by paying the customary cost for services received which was at a much higher rate than for members. There was no evidence of "any conscious effort to bestow" charity or benevolence on any person not connected with the organization though some persons did receive services without cost but according to the evidence that was due entirely to the inability of the association to collect from them for services previously rendered them. The association generally made an annual profit and this profit was used to increase its facilities and to reduce the cost of service to its members for the following year. The association instituted proceedings to force the county excise board of Beckham County, Okla. to exempt the association's property from ad valorem taxes. It claimed it was entitled to such exemption by reason of an Oklahoma statute that exempts from taxation All property, both real and personal of benevolent institutions or societies devoted solely to the appropriate objects of these institutions. From adverse determinations the hospital association appealed eventually to the Supreme Court of Oklahoma.

The sole question for determination here said the Supreme Court is whether the property of the hospital association was utilized for charitable or benevolent purposes. If so the property is exempt from taxation. Charitable is defined in 14 C. J. S. p. 407 in its broader sense as comprehending all kindly inclinations which men ought to bear toward one another, irrespective of class conditions and invidious distinctions. In 14 C. J. S. Charities p. 411 sec. 1 charity is said to embrace the sense of benevolence philanthropy and good will and good affections which men ought to bear toward mankind. Specifically a charity or charitable hospital is defined as one that is not maintained for gain profit or private advantage. 14 C. J. S.

Charities, p 422, sec 2c, and cases cited in the annotations, 61 C I 500, sec 597 et seq. It is generally said that "The character of the institution is to be determined, not done by the powers of the corporation as defined in its charter, but also by the manner of conducting the hospital." *Steward v California Med etc, Incn*, 178 Cal 418, 176 P 46. There is a wealth of cases, continued the court, and a variety of schemes of organizations and methods of operation, and many are held exempt and others are not. In all of them there is one factor the presence or absence of which means almost more than anything else in determining the issue. That is this: Are the doors of the hospital open to all, poor patients and pay patients alike? If the answer is yes, it is a charitable hospital and its property is entitled to the exemption from taxation provided, if the answer is no, it is not a charitable hospital and is not entitled to the exemption. In this instance the hospital association intended charity and benevolence and private benefit and advantage to its membership and to no one else. Whatever service it dispensed for which it received no pay was accidental or incidental. Its officers very carefully refrained from saying that its doors were open to the world irrespective of ability to pay. In speaking of private advantage as being a factor that precludes any organization from assuming the status of a charitable or benevolent institution, we mean private advantage to the organizers and the supporters thereof. The fact that a profit is realized from the operation of a hospital does not condemn the scheme as noncharitable or nonbenevolent. It is the use to which the profit is put that means much. In this case some of the profit is used to increase the facilities and some to the reduction of the cost to the members. This is a private advantage. The members of the hospital association here involved cooperated for their mutual advantage, but the record is bare of any evidence of an intent on their part to distribute charity or benevolence to any person not a member.

Accordingly, the hospital property was held to be subject to taxation—*In re Farmers' Union Hospital Ass'n of Elk City*, 126 P (2d) 244 (Okla., 1942).

Medical Practice Acts The Prescribing of Foods Based on a Diagnosis of Ailments Constitutes the Practice of Medicine—Pinkus, who holds college degrees and, in the words of the court, has studied "food chemistry and science, biology and physiology," conducted a store in Newark, N J, wherein food products were sold. On occasion, at least, he advised customers concerning their physical ailments and sold them certain "trade-name packaged" food products for the relief thereof. He was prosecuted for practicing medicine without a license in violation of the New Jersey medical practice act. At the trial, one witness testified that she told Pinkus that she had distress in her stomach and pressure around her heart and that he informed her that her condition was due to improper foods and that she should avoid starches and meats and eat "plenty of fruits and vegetables." He recommended and sold her a package of a product labeled "Sorbox." This witness testified that on another occasion she told Pinkus that she had a pain under both ears and down the side of her neck and that he informed her that her glands were not functioning properly and that she needed iron. He sold her a package of "Seatabs" and advised her to take one to four tablets daily. Later this same witness, so she testified, again visited Pinkus, informing him that she had an irritation around the waistline and had an itch. He told her that she had an acid condition, that she should not use any common table salt and that she should eat "lots of fruit, vegetables and lemons." He then sold her a package of "Vegebroth," advising her to use it twice a day. Two other witnesses testified to similar incidents and advice on the occasion of visits to Pinkus's store. Pinkus was found guilty of violating the medical practice act and prosecuted a writ of certiorari in the supreme court of New Jersey.

He contended that there was no evidence before the trial court of any violation of the medical practice act, that is, that his

acts did not amount to the practice of medicine and surgery as defined in the medical practice act. The practice of medicine, said the supreme court, is defined in the medical practice act as follows:

"Any person shall be regarded as practicing medicine and surgery, within the meaning of this chapter, who holds himself out as being able to diagnose, treat, operate or prescribe for any human disease, pain, injury, deformity or physical condition, or who shall either offer or undertake by any means or methods to diagnose, treat, operate or prescribe for any human disease, pain, injury, deformity or physical condition"—R S 15 918, N J S A 45 918.

In view of this language, we think it is clear that the acts of Pinkus did constitute the practice of medicine. Whether or not the substances he sold and prescribed are to be classed as medicines or not makes no difference. Clearly he attempted to diagnose the "physical condition" of the witnesses and to ascribe a cause for its existence and prescribe for such condition. Pinkus argued that he was merely engaged in the sale of food and food products because he had special knowledge concerning food. But, said the court, he went far beyond the mere sale of food when he diagnosed alleged ailments of the witnesses and expressed an opinion as to their cause. We think the practices engaged in by Pinkus came within the inhibition of the act.

Pinkus next contended that the section of the medical practice act defining the practice of medicine is unconstitutional in that it is unreasonable. The power of the legislature, answered the court, to regulate the practice of medicine has been upheld many times. The contention is now made that the language of the definition is so broad that it would prohibit the mere casual suggestion by one person to another of treatment that would help a condition described. However that may be, it is not being enforced in this case in any such set of circumstances. Here Pinkus was engaged in a commercial enterprise. He sold certain products and in connection with their sale attempted to diagnose ailments and conditions and to give advice as to dieting. We think there is nothing unreasonable in prohibiting this practice by other than licensed physicians.

The judgment of conviction was in effect affirmed—*Pinkus v MacMahon Judge*, 29 A (2d) 885 (N J, 1943).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1933 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be applied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Blood Pressure and Coronary Occlusion—Master and his co-workers investigated the blood pressure in 538 attacks of coronary occlusion. Slightly over half of the attacks were initial ones and the remainder were second or third attacks. The authors employed the following criteria in judging whether hypertension had been present before the attacks: (1) a systolic pressure of 150 mm or more at any time during observation; (2) a diastolic pressure of 96 mm or more prior to the attack; (3) a diastolic pressure of 90 mm or more during or after the attack; and (4) pronounced enlargement of the heart without obvious cause. It was found that the incidence of hypertension increased with age. The blood pressure fell in every case, but in a few the fall was slight. A transitory rise in pressure occurred infrequently at the onset of the attack. A rapid fall was somewhat more common than a gradual one. Occasionally the fall did not occur until after a week. The lowest pressure was usually reached between the twelfth and twentieth days. In some cases the initial fall was soon followed by a temporary or permanent rise in pressure. The trend of the blood pressure was similar in the hypertensive and non-hypertensive groups although a rapid fall was more common among the nonhypertensive patients who died. The systolic blood pressure rarely fell below 90 mm in the hypertensive group but this was common in the nonhypertensive group. When the pressure fell below 80 the patient usually died. In almost one fifth of the patients with a previous pressure of 200 mm or more the pressure did not fall below 150 mm. Two thirds of the hypertensive patients regained a hypertensive level in half of these this took place before discharge from the hospital, and in the remaining half usually within one or two years. The height of the blood pressure after the attack did not significantly influence the future course of the case with respect to subsequent angina pectoris, heart failure, coronary occlusion or death.

Thallium Poisoning—Gettler and Weiss state that, before proceeding to the actual detection of thallium, all organic matter in the tissue must be destroyed by an oxidative process. They list the procedures for the digestion of biologic material and describe the method which they found to be least time consuming and at the same time yielding a solution free of all organic substances. The various qualitative tests for thallium are critically reviewed. A detailed description for the detection of thallium in biologic material is given.

Meigs's Syndrome—Meigs and Cass reported in 1937 4 cases of ascites and hydrothorax associated with fibroma of the ovary. The serous effusions disappeared with removal of the tumor. In the years following the first presentation of this syndrome other cases were reported and brought to the authors' attention. The present report by Meigs, Armstrong and Hamilton lists 27 authentic cases. The syndrome is of considerable importance for some patients have died without proper surgical relief while others, doomed because of a tumor considered inoperable are now well. Two patients operated on in 1941 presented an opportunity to palpate the structure of the diaphragm and to collect fluid for investigation. The fluid in the abdomen and that in the chest were identical. Particulate carbon passed from the abdominal to the thoracic fluid quickly and easily. Three important investigative problems emerge from Meigs's syndrome: (a) the mechanism whereby ovarian fibroma gives rise to abdominal fluid; (b) the mechanism of the hydrothorax; (c) the question of whether similar mechanisms operate in combined hydrothorax and ascites when the primary pathologic condition is other than fibroma of the ovary. Cullen Kelly and others showed that fluid may be present in the abdomen with lesions other than ovarian fibroma. That this fluid is similar to the fluid found with fibroma has not been proved though it may be considered probable. In most cases of uterine fibroid with fluid there are adhesions or entanglement to the tumor or twists of the pedicle which were not present in the cases reported here. It remains for joint investigation by thoracic surgeons and others to demonstrate the presence of diaphragmatic perforations of small or large size or the presence of the rarely reported pleuro-peritoneal tubes.

Sulfadiazine Therapy of Pneumonia in Canal Zone—

Browne and his collaborators treated 100 consecutive unselected pneumonia patients in the Canal Zone with sulfadiazine. They utilized the original dosage recommended by the Council on Pharmacy and Chemistry, namely 0.10 Gm per kilogram of body weight initially, followed by 1 Gm every four hours day and night until a normal temperature had been present for seventy-two hours, at which time the chemotherapy was discontinued. There were 45 lobar and 55 bronchopneumonias. The average length of time between onset of symptoms and hospital admission was 4.07 days. Bacteriologically there were 42 typed pneumococcus (including 10 type I), 7 hemolytic streptococcus and 51 cases of undetermined etiology. The average sulfadiazine dosage was 40.5 Gm. The maximum sulfadiazine concentrations varied from 8 mg to 30.8 mg per hundred cubic centimeters. The temperature returned to normal by crisis within forty-eight hours in 78 patients, by lysis in 21 (one death). Pneumonia and drug complications with complete recovery in all cases were as follows: jaundice, 1; serous pleural exudate, 2; nausea and vomiting, 1. There was one death; a mortality rate of 1 per cent. Most noteworthy and inexplicable was the fact that 63 of the 100 patients developed a sinus bradycardia with occasional heart rates as slow as 36 beats per minute during or immediately following sulfadiazine treatment. The authors conclude that sulfadiazine is most efficacious in pneumonia that it is equally effective in the treatment of pneumonia in tropical as well as in other climates, and that it is accompanied by fewer drug reactions than sulfa-pyridine or sulfathiazole.

Gastroscopic Findings in Patients with Duodenal

Ulcer—Tumen and Lieberthal made gastroscopic studies on 50 patients with duodenal ulcer uncomplicated by pyloric obstruction. Of these 33 had chronic gastritis, 1 had unclassifiable inflammatory changes and 16 had normal stomachs. Six of the 16 patients with no evidence of gastritis had an atypical history or poor response to treatment or both. Twenty-one of the 33 patients with gastritis had an atypical history or poor response to treatment or both. While the incidence of atypical history and/or poor treatment response was somewhat greater in ulcer patients who had gastritis than in those who had not, it is difficult to ascribe much significance to this because among the 21 patients with gastritis who were examined by gastroscopy more than once the clinical severity of the symptoms seemed related to the gastroscopic picture in only 10. In the remaining 11 there was no correlation between the gastroscopic

picture and the presence or character of symptoms. The presence of gastritis did not regularly influence the clinical course of duodenal ulcer. It was impossible to postulate the presence or absence of associated gastritis on the basis of the nature of the symptoms or the character of the response to treatment.

Melanotropic Hormone and Vitiligo—The fact that the pituitary gland produces a melanotropic hormone and that dyschromia occurs in both hypopituitarism and hyperpituitarism led Fournier and his collaborators to investigate the possible effect of treatment with this hormone on vitiligo. The authors employed the hormone in 11 cases. Treatment was started by giving a local intradermal injection of 400 frog units twice a week. The beneficial effect consisted in a striking reduction in the area of the leukoderma. This therapy proved successful in 8 of 11 patients (73 per cent). One patient was given five bovine hypophyses orally. 9 others were given a purified extract of the hormone either locally or subcutaneously. The systemic action of the therapeutic measures is shown by the improvement in areas of vitiligo remote from the site of local or intradermal injections. Local ionization with the melanocyte hormone was tried successfully once. Improvement was more rapid and was of a greater degree in the patches which had appeared recently. Satisfactory results were likewise obtained in case of vitiligo of ten years duration.

Byssinosis—According to Boken the term byssinosis is applied to a form of respiratory disease affecting workers in cotton mills where much dust is given off in the processes of preparing the cotton for spinning and weaving. In the early stage the symptomatology is similar to the so called heekling fever, mill fever or Monday fever affecting workers in cotton mills. The onset is insidious. The victim sneezes frequently, develops a slight, dry, increasingly irritating cough and is aware of a feeling of constriction in the chest. Dyspnea becomes more pronounced. As the fine particles or strands of cotton become lodged in the lungs an irritation is set up and the breathing becomes more labored, the cough more metallic. The disease progresses with individual variation, over a period of years. As the cotton dust makes its way into the finer bronchi there is a decrease in vital capacity. The victim becomes a semi-invalid and is forced to give up work entirely. Before this stage of permanent disability is reached, however, many workers change their occupation. The author reviews the literature on byssinosis and presents the histories of 2 patients both of whom had worked for many years in the card room of a cotton mill. In 1936 an outbreak of respiratory disturbances among workers in a North Carolina mill called attention to the need of preventive measures to eliminate the health hazard. As reports from other mills appeared from time to time, steps were taken to control card room dust by installing vacuum strippers and grinders and ventilators. The workers are given frequent physical examinations, and those who exhibit excessive sensitivity to the cotton dust are urged to seek other employment. There is no specific treatment for byssinosis. Removal from exposure should be the first step if the worker appears to be susceptible, and then symptomatic or preventive treatment is instituted. In the late stages treatment can be at best only palliative, because irreversible structural changes have taken place in the lungs. Johnstone recommends for the treatment of dust diseases general tonics, vitamins, adequate diet, cough mixtures, mild narcotics and limited activity.

Treatment of Psoriasis—The method recommended by Brunsting is the combined use of crude coal tar byunction and of ultraviolet irradiation, a procedure first elaborated by Goeckerman. Crude coal tar ointment in a strength of from 2 to 6 per cent is used generally, excepting on the scalp and nails, where an ointment containing from 10 to 20 per cent ammoniated mercury is used. The patient is thoroughly bathed with soap and water to soften and facilitate removal of the scales. The trunk and extremities are thoroughly anointed with the tar ointment and suitable clothing is provided, such as loosely fitted underwear, pajamas or a covering of gauze. At bedtime additional ointment is applied to the body and scalp when needed. The next morning the tar ointment is smoothed with an oil to the consistency of a thin film over the entire body. Ultraviolet irradiation is carried out daily in increasing dosages. It is desirable to secure a brisk erythema short of a burn. Infiltrated plaques and the scalp may be subjected to more intensive treatment by protection of the surrounding skin by paper or cloth, but it is essential to irradiate the entire surface of the body. After the ultraviolet treatment a bath and shampoo again are in order and the ointments are reapplied. A considerable proportion of psoriatic persons also are subject to arthritis. The most common site of involvement in the early stages is the terminal phalanges of the fingers or toes, gradually the larger joints may become involved, even the spinal column, and when the disease is advanced the picture may resemble that of arthritis deformans. The treatment of psoriatic arthritis depends on prompt recognition and thorough control of the psoriasis by the use of crude coal tar and ultraviolet rays. The affected joints are treated as in other forms of arthritis. It

wise to bring into play all the auxiliary forces such as rearrangement of the diet and thorough elimination of foci of infection. Nonspecific treatment which provokes fever, such as hot baths, hyperthermia, or the injection of foreign protein is useful. Sun bathing is recommended strongly, and often a change to a sunny, dry and equable climate is beneficial. Roentgen therapy is practicable when there is early involvement of the joints or the hands and feet.

Subdiaphragmatic Abscess in Children—A subdiaphragmatic abscess complicating the postoperative course in a 3 year old boy with a ruptured appendix induced Ladd and Swan to review the cases previously seen at the Children's Hospital of Harvard Medical School. Fourteen patients have been seen in whom an abscess in the subdiaphragmatic space has been recognized. Eleven of these were treated surgically with one death, the other 3 had a fulminating infection and died. Post mortem a subphrenic abscess was found as one among multiple manifestations of a generalized sepsis. The symptomatology of subdiaphragmatic abscess showed considerable variation in the reviewed cases but it appears that in children at least three different types are encountered. These roughly parallel the different modes of origin of the infection. The first group comprises cases in which the subphrenic infection is part of a widespread intra-abdominal suppurative process. The second group in which the subphrenic infection complicates the course of an acute appendicitis with rupture of the appendix, is the type most commonly seen. The third group perhaps the most interesting and difficult to diagnose comprises cases in which the subphrenic abscess is metastatic and is at once the chief or only disease present. These patients have a history of upper respiratory infection, otitis media or recurrent superficial staphylococcal infection. This is followed some days later by the vague and insidious onset of mild malaise and anorexia associated with low grade pyrexia. These symptoms persist and there begin occasional attacks of abdominal pain. These symptoms gradually increase over a period of one to three months until the patient is brought to the hospital because of the appearance of a mass in the upper part of the abdomen. It is generally agreed that early and adequate drainage is the correct treatment for subphrenic abscess. In this series 11 patients underwent operation for drainage of a subphrenic abscess, with one death, a mortality of 9 per cent. There were 5 cases in which a direct incision was made and 2 in which the peritoneum was stripped from the diaphragm making 7 in which there was an extraperitoneal approach. These patients had a much shorter and better convalescence than did those who had a trans-serous approach. The extraperitoneal approach is the one of choice.

Dermatitis from Resin Glue in War Industries—Schwartz and his associates point out that an increase in the use of glues in the manufacture of wood substitutes has resulted in an increase in occupational dermatitis among workers in these industries. Glues can be classified with respect to their composition as (1) protein glues (2) natural resin glues (3) synthetic resin glues and (4) combinations of the foregoing. In the factories inspected in the course of this study the urea-formaldehyde and the phenol-formaldehyde resin adhesives caused most of the dermatitis. In making plywood for planes and gliders those who apply the cold liquid glues and those who apply the glue tapes are the ones most likely to be affected with dermatitis. The parts most often affected are the palms. The dermatitis begins in some workers as early as the third day after exposure (the primary irritant effect of the glue) while other workers may be exposed several weeks before it occurs. In factories where glass cloth is used workers though the glass fabric was the cause of the dermatitis but patch tests

showed that the phenol-formaldehyde molding powder was responsible. The treatment for dermatitis caused by glues is the same as for other forms of contact dermatitis. Where there are edema, vesicles and oozing only soothing wet dressings should be used such as solution of boric acid, solution of aluminum acetate (Burrow's solution) and 3 to 5 per cent tannic acid solution, this last on parts other than the face or neck. When the eruption begins to dry and crust mild fatty base ointments such as those of boric acid calamine or zinc oxide should be used. Workers with mild eruptions should be given protective clothing and should be treated on the job in order to give them the chance to become "hardened" (if the dermatitis is caused by allergy) and to learn how to protect themselves (if it is due to primary irritation). To prevent dermatitis the management should provide suitable exhausts to draw away all irritant dusts or fumes. Clean coveralls should be provided daily for workers exposed to irritant glues, dusts and fumes. Workers who apply the glues should be provided with impervious gloves made either of washable leather or fabric lined rubber and sleeves and aprons of impervious materials. The sleeves should fasten over the gloves at the wrist to prevent irritants from falling into the gloves. Facilities should be provided so that workers can frequently wash glue from the gloves and the skin. The brushes and the sponges used for gluing should be washed or changed about every two hours, and workers should be cautioned against touching the face and other parts of the body with glue soiled fingers, gloves or tools.

Renal Circulation After Compression of Renal Artery

—The purpose of this study by Corrigan and Pines was to check whether and to what degree the ischemia of renal tissue shares in the production of hypertension and, if not, which other factor can be made responsible for the appearance of high blood pressure. They examined the possibility of arterial hypertension being dependent on the relative increase of local venous pressure as compared to the pressure on the arterial side of the kidney. They sought to increase the venous runoff and to diminish the venous pressure after the Goldblatt maneuver had been performed. In order to accomplish this they elevated the kidneys sufficiently to straighten the course of the renal veins. This added the force of gravity to the vis a tergo in certain positions of the animal, prevented the collapse of venous walls and, by establishing a closer contact between the renal vein and artery, increased the effect of arterial pulsation on the movement of blood in the renal vein. This procedure was applied only to animals that had developed hypertension. In the first group of dogs the procedure was applied to kidneys the renal arteries of which were previously constricted, in the second group of dogs to the intact opposite kidney with simultaneous ligation of the renal artery so that both renal arteries

were ligated and only one kidney was elevated, and in the third group of dogs to the intact opposite kidney without ligating the ipsilateral artery, so that one renal artery was ligated and the opposite kidney elevated in the manner already described. In all cases there was a decided fall of blood pressure. These results were particularly striking in the second group, in which, following constriction of both arteries, a further increase of blood pressure could be expected. Results of their experiments are confirmed by the clinical experience of McCann and Romansky and of Riskind and Greene, who have established that the hypertension which accompanies the renal ptosis or renal torsion can be actively eliminated as soon as the incorrect position of the kidney is improved by a surgical operation or by an abdominal belt. The decisive factor, however, in the authors' opinion consists not in the reduction of the lumen of the renal artery because of the renal ptosis but in the impeding of the venous outflow in these conditions and in the fact that the restoration of the kidneys to their right place has had its effect on arterial blood pressure through improvement of the venous return. They conclude that hypertension depends on the disturbance of the balance between the pressure on the arterial and on the venous side of the kidney. When this balance is disturbed in favor of the venous pressure, stasis probably takes place in the renal capillaries and primary renal circulation is short-circuited through arteriovenous shunts. Consequently the tissue responsible for hypertension begins to suffer from inadequate supply of blood and production of a hypertensive substance is begun. When the balance between the pressure in the arterial and venous sides of the kidney is restored the production of hypertensive substance will cease, perhaps through reestablishment of an efficient oxygenation.

Sulfonamide Therapy in Actinomycotic Infections—

The 5 cases of actinomycotic infections reported by Lyons et al emphasize the necessity for long and continuous sulfonamide administration to effect healing and maintain remission of the disease. Sulfanilamide supplemented the surgical management of 5 patients infected with actinomycetes. The etiologic agent was an anaerobic *Actinomyces bovis* in 4 cases, one cervicofacial, one pulmonary, one pulmonary and abdominal and one abdominal infection. An aerobic non-acid fast actinomycete was found in another case in which there was an abscess of the buttocks. In every instance clinical improvement was noted within the first three weeks of sulfonamide treatment. This improvement was not maintained unless the sulfonamide compound was continued for a considerably longer period of time. Nine months of treatment with 4 Gm daily produced healing for two years in 1 case. Other patients treated with smaller doses for equal or longer periods of time showed recurrent abscesses and fistulous sinuses, but all patients appear improved. The dramatic initial response of these infections to sulfonamides is somewhat misleading. The drugs induce a remission and apparently diminish the intensity of the recurrence, but it can hardly be claimed that the disease has been completely cured. The necessity of surgical excision of the infection is clear. Surgical excision of all the infected tissue is the most effective treatment of the disease. Sulfonamide therapy is a valuable adjuvant to the surgical management of actinomycotic infections.

Bactericidal Action of Estrogens—Faulkner observed that diethylstilbestrol possesses some degree of bactericidal activity. Other substances possessing estrogenic properties were examined in order to see whether there was any correlation between the estrogenic and the bactericidal activities. Estradiol, estrone, diethylstilbestrol, hexestrol and diethoxytriphenylbromoethylene were investigated. The organisms used were all recently isolated from material sent to the laboratory for bacteriologic investigation. The strains of *Corynebacterium diphtheriae* were all virulent to guinea pigs. All the hemolytic streptococci exhibited beta hemolysis, and strains 4, 5 and 6 belonged to Lancefield's serologic group A. Faulkner states that diethylstilbestrol is bactericidal and in lesser concentrations bacteriostatic to gram positive cocci, *Corynebacterium diphtheriae* and *Neisseria catarrhalis*. No inhibitory action was noted on the gram negative bacilli. The minimal lethal concentration varies somewhat between these organisms, but in all those recorded it lies between 1:5,000 and 1:500,000. Tubercle bacilli were killed by incubation in vitro with diethylstilbestrol 1:5,000. Hexestrol also possesses bactericidal properties. Other estrogenic substances (estrone, estradiol and diethoxytriphenylbromoethylene) have not been found to have bactericidal action. The bactericidal activity of diethylstilbestrol is reduced in the presence of serum.

Method of Producing Experimental Granulating Wounds. H E Hutchison—p 75

Bacillary Dysentery—Bulmer and Priest assess the value of chemotherapy in bacillary dysentery on the basis of experience of eighteen months in the Middle East covering two summers. A sorting of cases by stool inspection shows two groups, there is the mildest type without blood and mucus in the stools familiarly known as Gypsy tummy and arbitrarily called acute catarrhal enteritis, this is an unpleasant condition often febrile associated with considerable abdominal pain and frequently needing hospital treatment. Even in this mildest type the stay in hospital of 600 patients averaged ten days. True dysentery is distinguished by the presence of blood and mucus in the stools

and is a much graver disease, the average duration of stay in the hospital of 600 patients was twenty days. A series of 483 patients with nonamebic diarrheas, the majority being bacillary dysentery, were treated with sulfonamide drugs. Of 323 patients treated with sulfaguanidine the average stay in the hospital was substantially reduced as compared with that of 600 controls. Of 97 patients with acute dysentery treated with sulfapyridine the stay also was reduced but the patients experienced nausea, vomiting and malaise. Of 63 patients treated with sulfanilamide the stay in the hospital was not reduced. The authors conclude that 1. Sulfaguanidine is a specific drug in the treatment of acute subacute and chronic bacillary dysentery, it is almost nontoxic and does not upset the patient. It is probable that its routine use would diminish the stay in the hospital by one half. 2. Sulfanilamide in the form of crushed tablets does not have any definite effect in dysentery. 3. Sulfapyridine is of considerable value in dysentery but is not so effective as sulfaguanidine. Its unpleasant effects make its use undesirable unless sulfaguanidine is not available.

Sulfapyridine in Sonne Dysentery—According to Swyer the incidence of Sonne dysentery has been increasing in Britain. Consequently any procedure which shortens the illness or reduces the number of carriers becomes of great importance. The series here described comprised 92 patients with Sonne dysentery, 57 of whom were treated with sulfapyridine and 35 were used as controls. Except at week ends daily bacteriologic examinations of feces and rectal swabs were done in all chemotherapy series, and twice weekly in controls, on desoxycholate-citrate agar. Treatment with sulfapyridine by mouth was instituted immediately on isolation of *Bacterium sonnei* and was continued until a negative report on the feces and on rectal swabbing was obtained. Administration of the drug was then stopped and after an interval of forty-eight hours further bacteriologic examinations were made. If these proved negative, examinations were repeated until a minimum of three consecutive negative stools and rectal swabs had been obtained. If after forty-eight hours the stool or rectal swabbing reverted to positive, the course of treatment was repeated. Careful watch was kept for toxic symptoms of chemotherapy, granulocytopenia being guarded against by leukocyte counts. In the chemotherapy group the average time required to obtain bacteriologic clearance was a fourth of that in the control group (five compared with twenty-one days). The period required to obtain apparently normal stools in the chemotherapy group was halved (nine compared with twenty days). No bacteriologic relapses after three days of the negative state arose in the drug treated patients but in controls six such relapses developed at periods ranging from seven to thirty-six days after apparent clearance.

Propamidine in Surgical Infections—Butler points out that propamidine has been shown to retain its bacteriostatic action in the presence of pus in concentrations which do not prevent phagocytosis, a property which makes it useful in the treatment of infected wounds. The drug is effective in staphylococcal infections and is extremely potent against the hemolytic streptococcus but is of little use against *Proteus vulgaris* and *Pseudomonas aeruginosa* in vitro against *Clostridium welchii* the activity is probably of the same order as against *Staphylococcus aureus*. The present paper describes a series of cases and suggests an additional method of using the drug. Two preparations have been employed a jelly or a solution. Of 10 cases reported 7 illustrate the value of propamidine jelly in the treatment of recent war wounds infected hands and certain types of bone infection. 3 show that a 1 per cent solution of propamidine injected into infected joint or empyema cavities may help to overcome the infection and sometimes make surgical intervention unnecessary. The jelly base of the propamidine preparation is a tissue irritant and must not be used if the wound is to be sutured. When used round open wounds it may cause redness of the skin which should be protected by petrolatum. If the drug is used for more than ten days the production of granulation tissue is often stimulated to an extent which is undesirable in superficial lesions but useful in filling up deep cavities. Propamidine jelly does not penetrate soft tissues or bone and is essentially a local bacteriostatic. Propamidine solution has mainly been used against staphylococcal infection.

 *Compensatory Myeloid Metaplasia of Spleen Importance of Differentiation from Chronic Myeloid Leukemia A. Pavlovsky—p. 287
 Sudden Death A. C. Tiquini and I. de Soldati—p. 328

Compensatory Myeloid Metaplasia of Spleen—Pavlovsky stresses the importance of a differential diagnosis between compensatory myeloid metaplasia of the spleen in aplasia of the myelopoietic organs and chronic myeloid leukemia. He observed 7 cases of the former condition and 99 cases of the latter. High voltage roentgen irradiation of the spleen, indicated in chronic myeloid leukemia, is contraindicated in compensatory myeloid metaplasia. A diagnosis of compensatory myeloid metaplasia of the spleen is made on clinical symptoms similar to those of chronic myeloid leukemia but of long duration, acute splenomegaly, changes in the peripheral blood similar to those of chronic myeloid leukemia or of chronic myeloid subleukemia, certain changes of the long bones and lack of tenderness over the sternum. The diagnosis should be verified by the examination of the sternal bone marrow and of spleen tissue obtained by puncture. The bone marrow is either aplastic or hypoplastic, whereas the splenic tissue is transformed into myeloid tissue. In 5 of the group of 7 cases of compensatory myeloid metaplasia of the spleen reported by the author, roentgen irradiations of the spleen were done. The 3 patients who received large doses of roentgen rays to the spleen rapidly developed symptoms of acute pancytopenia, aplastic anemia and thrombopenic purpura respectively. Immediate discontinuation of irradiation and attempts to control the disease failed. Two patients who had weekly irradiations with small doses rapidly grew worse. The symptoms were controlled by immediate discontinuation of the irradiations and the exhibition of hematomics. The last 2 patients and those given hematomics are living and are in a fairly good state of health. One of them is still living with compensatory myeloid metaplasia of more than twenty years' duration.

- Pathology of Brucellosis H. Tovar Mancera—p. 205
 *Natural Infection of Cats with Typhus L. Mazzotti and G. Varela—p. 229

Natural Infection of Cats with Typhus—Mazzotti and Varela experimented on domestic cats living in or near the wing for patients with infectious diseases in the General Hospital of Mexico City. Agglutination tests for *Proteus typhi* gave positive results with the blood of the animals. The tests were strongly positive with the blood of some animals. Guinea pigs inoculated with the brain of either cadavers of patients who died with typhus or of rats that had been previously inoculated with the brain of the cats developed fever and scrotal inflammation (Neill-Mooser positive sign). Extracellular and intracellular rickettsiae in large numbers were observed in cultures of the tunica vaginalis of inoculated guinea pigs. The authors direct attention to the presence of natural typhus in domestic cats and the possible role of these animals as temporary reservoirs of typhus. Natural infection of cats probably occurs through fleas or through ingestion of infected material.

 *Procaine Hydrochloride Spinal Anesthesia and Altitude P. Perovic—p. 706
 Traumatic Hernia of Testicle D. Calisti—p. 709

Spinal Anesthesia and Altitude—Perovic found that the effects of spinal anesthesia induced with procaine hydrochloride diminished with increase in altitude. The dose varies in the following proportions: from 0.08 to 0.10 Gm at altitudes of 500 meters over sea level, from 0.10 to 0.12 Gm at altitudes between 1,000 and 1,500 meters, from 0.12 to 0.14 Gm at altitudes between 2,000 and 2,500 meters, from 0.14 to 0.16 Gm at altitudes between 3,000 and 4,000 meters and from 0.14 to 0.17 Gm at altitudes over 4,500 meters above sea level. The

author believes that increased altitude causes increased concentration of organic and chemical substances in the cerebrospinal fluid, which is the factor in diminishing the effect of the anesthetic on the central nervous tissues.

 Sulfanilamide in Surgery J. Nasio—p. 157
 Antidiuretic Action of Pitressin in Acute Nephritis R. Q. Pasqualini and A. C. Astrogdro—p. 168
 Therapy of Obstetric Shock G. Ricci, N. Rodriguez Miranda and M. Balaguer—p. 175

Pulmonary Blastomycosis with Cavitation—According to Capdehourat and his collaborators pulmonary blastomycosis with cavitation is rare. The case they report is the second in the literature. A woman aged 26 presented symptoms simulating pulmonary tuberculosis of five years' duration. The bacteriologic examination of the sputum was negative for tubercle bacilli but showed numerous monilia. X-ray examination of the lung showed a shadow of a large solitary cavity. Sulfonamide therapy was without effect. Intravenous injections of chiofon in doses of from 5 to 10 cc and sodium iodide or potassium iodide in daily dose of 0.4 Gm brought about a clinical and roentgenologic cure of the patient. Repeated x-ray examinations of the lung demonstrated disappearance of the cavity more than eight months after discontinuation of the therapy.

 *Malignant Exophthalmos P. Sunder-Plassmann—p. 88
 *Fatigue Fractures and Zones of Transformation in Bone F. Schroder—p. 92

Malignant Exophthalmos—According to Sunder-Plassmann there are cases of exophthalmic goiter in which the exophthalmos continues to increase after removal of the thyroid. These are cases of malignant exophthalmos. In the mild form of malignant exophthalmos conjunctival excision has been effective, but there are also cases in which the exophthalmos increases to a point of perforation of the eye. The author reports a case in which enucleation of the eyes became necessary. In another case conservative measures proved ineffective. Both eyes had advanced corneal ulcers, and spontaneous perforation seemed imminent. The patient required morphine for the control of the pain. The visual capacity was practically nil. As a last resort it was decided to attempt the operation described by Naffziger in 1933, which that author had successfully employed in 6 cases. Bilateral trepanation was done and then by the intracranial approach complete orbital decompression was effected, also decompression of the roof of the nerve canal. As had been observed by Naffziger, the eye muscles were enormously enlarged and both optic nerves showed extreme edema. The patient tolerated the operation well. The exophthalmos receded rapidly, and complete closure of the eyes became again possible. The corneal ulcers healed. The patient regained normal visual capacity and her general condition is excellent.

Fatigue Fractures—Schroder shows that the pathologic changes caused by overexertion of bones become manifest in two distinct forms as fatigue fracture and as "umbauzone" (zone of transformation). The fatigue fracture represents a typical fracture. The fracture line is usually delicate, there is considerable callus formation and the pain is severe. The zone of transformation shows a wide area of reduced density, but there is only slight or no callus formation and mild pain. Both lesions are observed at the characteristic sites of greatest exertion, but, whereas fatigue fracture occurs only in healthy bone tissue, zones of transformation develop chiefly in the presence of metabolic disturbances or deficiency diseases. The author reports that zones of transformation appeared in both scapulas, both rami of the os pubis and on the eighth rib on the left side of a woman aged 42. These zones of transformation disappeared after prolonged treatment with vitamin C, and it is concluded that vitamin deficiency played a part in their development.

Book Notices

Health and Physical Fitness By I. H. Goldberger, M.D., Assistant Director of Health Education, New York City Public Schools, and Grace T. Hallock, Director, Welfare Publication Bureau, Metropolitan Life Insurance Company. Cloth, Price \$1.92, Pp. 596, with illustrations. Boston: Cinn and Company, 1943.

This book by two authors experienced in health education is designed specifically to contribute to the training in health and physical fitness of the high school Victory Corps and in general for high school health education programs. It follows a conventional organization of such textbooks but is exceptionally rich in well conceived illustrations used in the modern manner, including bleedoff, montage, diagrammatic section and partial section techniques. Each unit has a challenging set of questions under the title 'What Would You Think Say, or Do If—' and under each of these titles such challenging questions as "A 4 year old child of your acquaintance lost a tooth and his mother said 'It doesn't matter he'll get another to take its place'." There are also matching tests, true-false selections, completion tests, extensive suggestions for further study and discussion, and a list of scientific words of which to learn the meaning. Each unit is introduced by a set of "leading questions." The units are effectively entitled, for example, the unit on vision is called "Look!" and, in the same manner, that on hearing 'Listen'. The book is interestingly presented and thoroughly practical. It should be a valuable teaching help.

The Pharmacology of the Opium Alkaloids. Part 2 By Hugo Krueger, Assistant Professor of Pharmacology, St. Louis University School of Medicine, Nathan B. Eddy, Principal Pharmacologist, U. S. Public Health Service, and Margaret Sumwalt, Associate Physiologist, U. S. Public Health Service. Supplement No. 165 to the Public Health Reports, Federal Security Agency, United States Public Health Service, Division of Sanitary Reports and Statistics. Cloth, Price \$1.50, Pp. 813, 1448. Washington, D. C.: Supt. of Doc. Government Printing Office, 1943.

The first part of this book offered a dissertation on morphine which provided an excellent informative source for reference. The second part is intended to supplement the other volume and offers concise presentation of pertinent data on codeine, ethylmorphine, dihydromorphine, diacetylmorphine, thebaine, apomorphine, other derivatives of morphine, sinomenine and its derivatives, papaverine and its derivatives, narcotine and its derivatives, narceine and its derivatives, cryptopine and protopine. The book is not for the practicing physician unless he has an unusual interest in the opium alkaloids; it should be available for all teachers and researchers in pharmacology and therapeutics. The material is presented in concise form and its accumulation must represent the labor of almost uncountable searches into the literature by the authors. The bibliography, subject and author indexes are as complete as the reviewer has ever seen.

Urology in General Practice By Nelse F. Ockerblad, B.S., M.D., F.A.C.S., Professor of Clinical Urology, University of Kansas School of Medicine, Lawrence, and Hjalmar E. Carlson, B.S., A.M., M.D., Instructor in Urology, University of Kansas School of Medicine. Cloth, Price \$4. Pp. 333, with 98 illustrations. Chicago: Year Book Publishers, Inc., 1943.

Had the authors of this little volume adhered to their promise as stated in the preface 'to help the general physician do better those things that are within his province in the realm of genito-urinary diseases and to suggest the limits beyond which the best interests of his patients require that he obtain the help of a specialist,' this might have been a book of value but unfortunately they fall far short of the mark. The text starts with the most elementary details of laboratory diagnosis and presently one finds an adjoining chapter on such subjects as kidney ptosis, anomalies of the genitourinary tract and urinary lithiasis, the subject matter of which might cause even a research worker to ponder. The reviewer takes issue with the discussion of nephritis. This chapter may be comprehensive but it has no place in urology. Nephritis is a medical disease. There is no sequence whatever to the arrangement of the subject matter, no orderly presentation, even though isolated topics are well discussed. It is most unfortunate that an experienced urologist should write about diseases of the male urethra to the complete exclusion of pathology of the verumontanum about which the general practitioner should know, even though he is not equipped to treat it, and so on. In brief this book is neither fish nor fowl, it is smörgåsbord.

Index to Dental Literature in the English Language Including One Hundred and Twelve Periodicals from Australia, Canada, England, India, South Africa and the United States, Three Years, 1939-1941. An Alphabetical Subject and Author Index. A List of Dental Books. Committee on Library and Indexing Service of the American Dental Association. John E. Gurlev, D.D.S., Chairman. Cloth, Price \$7.50, Pp. 282. Chicago: American Dental Association, 1943.

The American Dental Association is to be congratulated on the appearance of this volume of the "Dental Index," covering the years 1939 to 1941, in which a change of style has been effected. Instead of the former numerical system of classification the arrangement is alphabetical according to author and subject. Listing of entries under subjects by title rather than by author and the use of continued column heads would have improved the make-up still further. The subject headings are practical rather than scholarly, but they represent nomenclature in current use. It is hoped that certain wordy headings, inconsistencies in indexing and similar technical defects will be eliminated in future volumes.

How to Prepare for Military Fitness By Lieutenant Colonel François D'Ellsca, Illustrated by Stephen J. Voorhes. Cloth, Price \$1.96, Pp. 216. New York: W. W. Norton & Company, Inc., 1943.

In this compact volume there is an excellent, well edited and adequately illustrated description of the more important methods of physical training. The material is carefully selected from among the more beneficial forms of calisthenics and conditioning exercises as they apply to military personnel. Descriptions of drills, exercises and games are concisely vivid and accurate. The author has subtly drawn on his own experience to add to the effectiveness of the instructions given. Wall scaling and tree climbing, elementary judo, wartime wrestling and boxing, unarmed defense and disarming an opponent are especially valuable and timely chapters. Further, to meet current needs, the last portion of the book adequately describes swimming and life saving procedures to be employed in common situations which soldiers and sailors are apt to encounter. Throughout there are many well drawn black and white illustrations which clarify the subject. On the whole it is an excellent handbook on physical training that deserves a wide circulation.

Your Own Story By Marlon L. Faegre, Assistant Professor of Parent Education, Institute of Child Welfare, University of Minnesota, Minneapolis. Paper, Pp. 52, with illustrations. Minneapolis: Minnesota Department of Health, 1943.

This booklet contains a brief story of human and animal reproduction—not animal and human—to which thirty-one of its fifty-two pages are devoted. The remainder is a chapter addressed to parents as to how to use the material in the first part of the pamphlet. The pamphlet could not be more effectively reviewed than in the words of Dr. Haven Emerson contained in its introduction: "Other states and in fact our federal agencies promoting human welfare could not do better than follow Minnesota's example and compete in friendly rivalry of word and design to carry to all parents and children lessons of the hygiene of human reproduction and the bearing of our bisexual structures and functions on personal, family and social soundness of character and happiness. What is here offered is to be unreservedly accepted and recommended for its accuracy and directness of statement and for the spirit and purpose of the language and illustrations used."

Memoirs of a Guinea Pig or Eight Years in a Doctor's Waiting Room By Howard Vincent O'Brien. Cloth, Price \$2, Pp. 238, with illustrations by Robert Mills. New York: G. P. Putnam's Sons, 1942.

In his middle 40's Mr. Howard Vincent O'Brien, who is a clever writer developed difficulty with his vision—a condition commonly referred to as scotoma. In his search for relief he tried everything including shock therapy, heat therapy, allergy, manipulation of the feet, vitamins, osteopathy, chiropractic and procedures directed toward the intestines and the gallbladder. Apparently he comes to the end of 237 pages still with the scotoma, also with the ability to write an intensely human chapter on 'The Care and Feeding of Doctors.' Here he disports himself by injecting a few barbs into some of the easily recognized and significant weaknesses of the profession. In the course of his travels he came also under the attention of some of our leading ophthalmologists who will be recognized not only by the mention of their names in the dedication but also by their characterization in the work. This item is recommended especially to ophthalmologists with a sense of humor but also to every doctor with a sense of humor.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMETE T AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODY. I HAVE SPECIFICALLY STATED IN THE REPLY. A. O. S. COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THIS WILL BE OMITTED ON REQUEST.

RUPTURE OF MEMBRANES TO INDUCE LABOR

To the Editor—For over five years my colleagues and I have been inducing labor by artificial rupture of the membranes when we felt that this was indicated, that is, mainly when the child is past due with the head engaged or there is a plus 1 or plus 2. After the reorganization of our hospital staff we were told that this is poor obstetrics and will no longer be tolerated. We have never had a complication, which is probably due to the fact that we have never used this method promiscuously. We are interested mainly in determining whether or not this is generally considered a poor obstetric procedure. We should appreciate an opinion that will help answer this problem. If this procedure is poor obstetrics we wish to discontinue it, however, the fact that we have used it successfully for over five years leads us to believe that we are not in error. Does the literature substantiate our confidence in this method?

M D, Illinois

ANSWER—Artificial rupture of the membranes has become the accepted method of inducing labor when this procedure is indicated. Ideally, the following conditions should be present:

The pregnancy should be advanced to term or beyond it. There must be no question of cephalopelvic disproportion. The cervix should be "ripe", that is, it should be well effaced and sufficiently softened to admit one or two fingers. The head should be engaged. When these conditions are present there is little hazard in the induction of labor. The latent period is rarely long and the labor is of average or shorter than average duration.

The real hazards occur when the indications mentioned are not present. Rupture of the membranes in the absence of a "ripe" cervix may lead to a long latent period and a prolonged and occasionally complicated labor. If the presenting part is not well engaged in the pelvis, prolapse of the umbilical cord may and does occur. The abnormal labor will increase the hazards of infection. The method is most successful at or near term and becomes less and less successful the further away from term it is attempted.

The induction of labor should be reserved for patients for whom such a procedure is indicated. Although it can be carried out with little risk in properly selected cases, it is far better to allow normal patients to go into labor spontaneously. The induction of labor for postmaturity is rarely indicated.

SNUFF HABIT

To the Editor—A woman aged 58 wishes to break the long standing habit of using snuff. Is there any medication which may assist her in her problem?

August C Orr, M D, Bismarck, N D

ANSWER—Whether the cessation of the snuffing habit is desired for social, esthetic, economic or hygienic reasons, the measures advised must be psychologic and environmental more than pharmacologic. The craving for nicotine may be alleviated by replacement with lobeline hydrochloride, though the lobelia addiction may be just as undesirable. The motor component of the snuff chewing habit may be replaced by that of chewing gum or candy. The use of pepper and other sternutatories instead of snuff has not met with favor. The development of unpleasant associations by giving ill smelling, ill tasting or unpleasant acting drugs such as asafetida, aloin or apomorphine with the tobacco has been suggested, as in a popular treatment for alcohol addiction. Painting the throat with silver nitrate causes a bad taste on attempting to smoke, but this effect may not be found on chewing or snuffing.

Lessening of the availability of the supply or of reminders of its use, and increase in other interests to distract attention and lessen the impulse to the use of the snuff may be of aid. Clarification and reinforcement of the conscious reasons for abandoning the habit, and encouragement of the individual to develop and display her will power in this connection may be effective.

CORONARY DISEASE DIFFERENTIATED FROM DIAPHRAGMATIC HERNIA

To the Editor—A man aged 66 has coronary disease but is otherwise in excellent condition. What are its classic and differential symptoms compared with those of diaphragmatic hernia? Compared with the incidence of coronary disease, about what is its ratio to that of diaphragmatic hernia? What type of therapy would you regard best suited for a diaphragmatic hernia diagnosed as such in a patient as here briefly described?

C B Greear, M D, Honaker, Va

ANSWER—The classic symptoms of coronary disease are substernal pain with radiation to the left shoulder and arm or, less frequently, to the right. There may also be radiation to the neck and jaws. The pain is usually associated with a sense of oppression. This pain is usually precipitated by exercise and particularly by exercise shortly after eating. The practical difficulty lies in the fact that there are so many variations from the classic picture. This pain or one of its variations can be differentiated from that of diaphragmatic hernia in many cases only by visualizing the hernia. In fact, it may be that the pain of diaphragmatic hernias is really due to reflex coronary constriction. It is impossible to say what percentage of coronary pain is caused by diaphragmatic hernias, but such a cause is sufficiently frequent to warrant the search for diaphragmatic hernia whenever possible. The symptom that most often arouses suspicion of diaphragmatic hernia is coronary type of pain that comes on with the patient recumbent and which is relieved when the patient assumes an upright position. X-ray examination is, however, the final diagnostic test for diaphragmatic hernia. Active treatment of such hernia is not satisfactory. In most cases coronary dilators plus palliative treatment will cause an amelioration of symptoms.

DERMATITIS FROM WEEDS OF RAGWEED GROUP

To the Editor—A patient has a contact dermatitis from weeds. On patch testing he is sensitive to western ragweed, Santa Maria feverfew, crane's bill and burweed marsh elder. Kindly let me know in what parts of the United States he might live where all these weeds are absent or present only in small numbers.

M D, Colorado

ANSWER—Western ragweed (*Ambrosia psilostachya*) is widely distributed over the western half of the United States. It is not abundant east of Oklahoma, Kansas and the Dakotas except perhaps in western Minnesota.

Santa Maria feverfew (*Parthenium hysterophorus*) is common throughout the Southern states as far west as Texas, being found in southern Missouri, southern Illinois and in the area south of the Ohio River.

Crane's bill, or wild geranium (*Geranium spp*), covers a genus of some ten species, several of which are common throughout the Eastern, Northern and Central states.

Burweed marsh elder (*Iva xanthifolia*) is a ragweed which grows abundantly in the northern Mississippi and Missouri valleys and in many places in the intermountain states.

There is no appreciable area where all four plants are absent. Locally one might find plenty of places where over a limited area none of the plants would be present—for example, in a wooded section in the Rocky Mountain area or a seacoast locality such as Miami, Fla. Since the allergy in question involves contact with the plant it should be easy in almost any large city to avoid all four offenders. Cleveland would be free from all except crane's bill, and this would probably be found only in wooded parks or forest preserves. However, the close relationship of western ragweed to common ragweed would suggest caution in close exposure to the latter, which is, of course, widely distributed over the Eastern states.

GASTROINTESTINAL SYMPTOMS AND GRASS EATING

To the Editor—A boy, aged 13, had vague lower abdominal discomfort. His appendix had been removed. Temperature, pulse and respiration were normal. There was some constipation and some dysuria but nothing in the urine. After three days' rest and a bland diet he was symptom free. On the morning of my last visit I saw that he had a pocket full of green grass, which, it developed, he had been in the habit of putting in his mouth. It was denied that he actually chewed it. Is there anything in grass that might produce gastrointestinal symptoms or genitourinary symptoms if the grass should be tasted or chewed?

M D, Massachusetts

ANSWER—W C Muenscher (Poisonous Plants of the United States, New York, Macmillan Company, 1939) mentions a number of grasses as poisonous under certain conditions. These include *Sorghum vulgare* (sorghum), *Sorghum halepense* (Johnsongrass) and *Holcus lanatus* (velvet grass, mesquite grass) which may cause poisoning as the result of the formation of prussic or hydrocyanic acid on hydrolysis.

Lolium Temulentum L (darnel, tares, poison rye grass) is widespread in the United States, contains the toxic alkaloid temuline. According to some authorities darnel is poisonous.

only when infected by the fungus *Endoichidium temulentum*. Apathy, sleepiness, giddiness, mydriasis, nausea and vomiting followed by abdominal cramps have been ascribed to dandel poisoning in human beings.

Ergrostris cilianensis (stink grass meadow snake grass) and *Stipa robusta* (sleepy grass) may cause poisoning in horses but the animals always recover.

Toxic symptoms may be produced also by poisonous weeds eaten with grass and by rusts, smuts and molds present on grass.

Most ordinary grasses such as are found on city lawns (for example, June, crab and orchard) aside from producing a bitter taste in the mouth are not harmful. Of course if eaten in sufficient quantities mechanical disturbances of the intestine may result. It is of interest to note that grass either in chopped form or as tablets prepared from dried and powdered grass, may be ingested by human beings without untoward effects. Similarly the juice extracted from grass has been administered to both children and adults without ill effects.

Although the nature of the grass is not mentioned it seems unlikely that it is a member of the poisonous group. In all probability the patient's symptoms were entirely unrelated to the tasting or chewing of grass.

PLASMA ELECTROLYTES

To the Editor—What are the normal limits of plasma electrolyte millimols?
Captain M. C. A. U. S.

ANSWER.—The total plasma electrolytes equal the sum of the positively charged cations and negatively charged anions in solution in plasma. In considering acid-base balance it is convenient to use a unit of concentration which reflects the equality between the total positive and total negative ions and permits the comparison of concentrations of different ions in units that are electrically equivalent. Hence in discussing plasma electrolyte concentrations the unit milliequivalent is preferable to the unit millimol. A milliequivalent equals a millimol divided by valence. Milliequivalents may be derived from milligrams per hundred cubic centimeters as follows:

$$\frac{\text{mg per 100 cc} \times 10}{\text{molecular weight}} = \text{millimols per liter}$$

$$\text{millimols per liter} \times \text{valence} = \text{milliequivalents per liter}$$

The following table gives the upper and lower limits of plasma electrolyte concentrations expressed as milliequivalents per liter.

	Base meq/L.		Acid meq/L.
Na ⁺	136.0-144.0	HCO ⁻	25.0-27.0
K ⁺	4.0-5.0	Cl ⁻	98.0-106.0
Ca ⁺⁺	4.8-5.2	HPO ⁺⁻	1.8-2.5
Mg ⁺⁺	2.5-3.5	SO ⁺⁻	0.8-1.2
		Organic acid	4.0-8.0
Average total	155	Protein	14.0-18.0
		Average total	155

IRRITATION FROM COAL TAR OR PINE TAR

To the Editor—I have had contact eczema dermatitis on my hands for two years. It was due to tar. Will you kindly give me information on coal tar products or products with the benzene ring.

Alfred A. Newberry M.D. Twin Falls Idaho

ANSWER.—The query is rather an indefinite one because there are at least two types of tar, coal tar and pine tar which differ somewhat in composition. Neither of the tars is a chemical entity, they consist of a great many hydrocarbons.

A great many chemicals are derived from tar either directly or by chemical combination.

Many of the chemicals in tar will irritate the skin and many of them will sensitize the skin. Some of them are photosensitizers.

It would be desirable to find which of the ingredients of tar cause the trouble. This can be done by performing patch tests first with coal tar itself to verify the diagnosis, second with the coal tar distillates and third with the basic chemicals found in the particular distillates which show the strongest reactions from the patch tests.

FUNCTIONS OF VERTEBRAE AND ARTICULATING PROCESSES

To the Editor—Following a fall from a horse and in turn having the horse fall on me I received a slight fracture of the body of the fourth lumbar vertebra that is the superior lip was pushed down approximately an eighth of an inch slivering the bone parallel and under the anterior longitudinal ligament. The injury has been remarkably free from any pain or discomfort which is more than I can say for the treatment that has been directed toward keeping my lumbar spine in a mild degree of hyperextension. I have been struck with the fact that all of my colleagues seemed to be particularly obsessed with an assumption that the bodies of the vertebrae are principally supporting blocks to the upright position or rather erect posture. My contention is that all of the antigravitational force is centered in the articular processes at the root of the vertebral arches and is balanced antigravitationally in the supraspinal ligaments evolving the anticlinal vertebra in other words the bodies of the vertebrae and the intervertebral disks are progravitational reducing the function of the body and the intervertebral disk to a cushioning counterbalancing and shock absorbing rather than supporting. Sir Samson Wright in Applied Physiology discusses this question in his chapter on muscle tone and regulation of posture from the standpoint of muscles and nerves but does not correlate this with any physical structure of the bones. To reexamine the foregoing assumption what are some of the recent opinions as to the importance of the bodies of the vertebra in maintaining the erect posture?

H. D. Allen Jr. M.D. Milledgeville Ga.

ANSWER.—There is a difference of opinion as to just what the total functions of the articulating processes at the bases of the vertebral laminae are. The probabilities are that they have little to do with the actual weight bearing. Weight bearing most probably is taken care of through the bodies of the vertebrae and the intervertebral disks. The chief function of the articulating processes is that of preventing a forward slipping of the upper vertebra on the one below.

In neurosurgery it is often necessary to perform a wide laminectomy in which the articulating facets (articular processes) are removed on both sides and the patients get along well. The old question comes into prominence here as to whether or not ligaments give the most support or the muscles. Both are essential. The spinal bony column is made up of a number of separate bones, one on top of the other, held together by their contour and strong reinforcing ligaments. In a way the spine can be likened to a tent pole and the muscles to the guy ropes that hold the pole erect.

Clinically, it has long been known that a slight compression fracture along the anterior border of a vertebra may give little or no discomfort and treatment in such cases by hyperextension is not necessary.

FOCAL (ESPECIALLY DENTAL) INFECTION AND NEPHROLITHIASIS

To the Editor—What are the possible relationships between infections particularly pyorrhea and nephrolithiasis? Two articles have come to my attention one in the January 1943 issue of the Merck Report by G. de Leo M.D. urologist Columbus Hospital New York and an article which appeared in the Dental Cosmos for November 1931 entitled Dental Focal Infection as an Etiological Factor in Diseases of the Genitourinary System by Herbert Sugar M.D. Los Angeles. A question has recently arisen in a case in which there was a definite history of nephrolithiasis from a period of over eighteen years which eventuated in the surgical loss of one kidney. Pyorrhea preceded and was coincident with attacks of renal colic and passage of gravel for the first three or four years. Specifically could this pyorrhea be considered as having an etiologic bearing on the kidney condition?

M.D. Montana

ANSWER.—Many factors are involved in the etiology of nephrolithiasis. Infection of the urinary tract is undoubtedly important in recurrent stone formation particularly when urea splitting organisms are present for example *Proteus vulgaris*, *Escherichia coli*, *staphylococci*, *Bacillus pyocyanus*, *Hemophilus influenzae* and certain streptococci. There are various possible sources of origin for these bacteria, among which the colon must be given a prominent role.

Ever since the experimental production of renal calculi in dogs by streptococcal infection of devitalized teeth (Rosenow and Meisner) many clinicians have accepted the theory of focal dental infection including pyorrhea as a factor in nephrolithiasis. Search of the literature does not reveal significant factual support for this view. Ordinary statistical studies prove nothing in view of the high incidence of pyorrhea and its resultant coincidence with many other diseases. Another difficulty is the fact that the bacteria found in dental infection are usually streptococci while the organisms found in the urine of individuals with stones are likely to be colon or proteus bacilli or staphylococci (Kessler). However streptococci have been found by means of the Gram stain in a large proportion of calcific plaques on renal papillae (E. C. Rosenow Jr.). The significance of this observation is highly debatable apart from the fact that no deduction is possible regarding the origin of the bacteria in this series of cases.

It would therefore seem unwarranted to conclude that the patient's pyorrhea had an etiologic bearing on his nephrolithiasis.

sis On the other hand, one could not draw the opposite conclusion in this specific instance. Carefully controlled clinical observations early in the course of kidney stone formation, are badly needed.

DESTRUCTIVE LESION OF TERMINAL INTERPHALANGEAL JOINT

To the Editor—A patient aged 48 has had swelling and discharge from the right middle finger for the past six months. This discharge has the appearance of joint fluid. An x-ray film shows that there is rather extensive destruction of the terminal interphalangeal joint of the right middle finger. There is also evidence of some slight bony destruction in the opposing bony surfaces. This involves both the terminal and the middle phalanx. There is no evidence of any osteomyelitis. The findings in this case are quite typical of infectious arthritis. The condition is suggestive of osteoperiostitis aluminosa. With these findings, could you suggest the best method of treating this condition?

R. V. Jolin, M.D., Grand Rapids, Minn.

ANSWER—Tuberculosis of a single interphalangeal joint is more common than is the condition referred to as osteoperiostitis aluminosa. Destruction of a finger joint without new bone formation in the region should be considered tuberculosis until proved otherwise. A biopsy is indicated. If the diagnosis is confirmed, amputation of the distal phalanx will give the most certain and most prompt recovery of use of the hand. The alternative method of treatment is long continued splinting of this finger in a position of slight flexion. It should be remembered, however, that a fused interphalangeal joint is a much more serious handicap than is the loss of the distal phalanx of a finger.

PRESERVATION OF LIQUID PLASMA

To the Editor—How long can properly processed liquid plasma be safely kept on a shelf at room temperature and at average refrigerator temperature? Also how often should such plasma be cultured for sterility?

M.D., District of Columbia

ANSWER—The preservation of plasma in the liquid state should be avoided as much as possible.

In any case liquid plasma should not be preserved at refrigerator temperature, because of massive irreversible flocculation. If very thorough sterility tests have been performed, the expiration date for liquid plasma kept at room temperature (15 to 30 C) has been set at one year by the National Institute of Health.

It is not necessary to repeat the sterility tests if proper cultural studies were done at the time of pooling the plasma and if the material was not subsequently exposed to contamination.

COCCYGEAL INJURY AND TRAUMATIC ARTHRITIS

To the Editor—A man aged 71 fell out of bed and struck on the lower part of his spine. Considerable pain and disability followed, and an x-ray examination showed a fracture of the last bone of the coccyx—not straight across the bone but slanting. A few weeks after the original injury tenderness developed in one of the lower lumbar vertebrae on pressure, x-ray examination showed no signs of fracture or dislocation, but there was evidence of arthritis. The patient's general condition is fairly good, but it is difficult for him to get about, his legs feeling weak and a certain numbness being present. Bowel and bladder functions are good and with the aid of vitamin B₁ his appetite is satisfactory. I shall appreciate any advice or suggestions for treatment of this patient. Can you give any estimate as to the length of disability?

F. S. Spearman, M.D., Williams, Ariz.

ANSWER—The fact that the pain is in the lower lumbar area would indicate it is not a coccygeal injury that is causing the pain. The discomfort may be due entirely to the arthritis in the lumbar part of the spine, the fall being the contributing factor, causing a traumatic arthritis on top of the old. There is no specific treatment but rest, not necessarily to the point of rest in bed but to the point of moderation in activities, and application of heat to the affected area, preferably radiant heat, along with gentle massage, will do as much as anything. In a man of this age metastatic cancer must be considered, and a careful examination of the prostate and inquiry as to gastrointestinal symptoms should be carried out. The length of disability is difficult to estimate, but if traumatic arthritis on top of old osteoarthritis is the basis, the patient should experience considerable improvement in a few weeks.

REACTION TO PITRESSIN TANNATE

To the Editor—A woman aged 40 has diabetes insipidus. I am giving her pitressin tannate into her gluteal muscle. Six months ago she had a reaction. Yesterday she had another reaction from the injection. These reactions came on immediately after taking the injection. I did not see her immediately, but at the time I saw her she had a fever, felt cold and had a feeling of constriction in her chest. Her blood pressure was normal. A small injection of epinephrine increased her discomfort. I gave her a small amount of morphine, after which she felt warm and had some relief. I feel sure this was not a hysterical manifestation, as her temperature was almost 102 F. It seemed to me to be a foreign protein reaction. She remained ill for twenty-four hours, at the end of which time she seemed completely recovered. She is taking these injections at forty-eight hour intervals. Can you give me any more information about this type of reaction, the probability of its recurrence and the probability of its being fatal? What is the treatment? M.D., Iowa

ANSWER—The literature relating to the use of pitressin tannate for the treatment of diabetes insipidus is listed below. Reaction to this type of treatment has not been reported. The best suggestion to follow would be to abandon this type of treatment in this particular case and to institute the use of posterior pituitary powder by nasal insufflation. A small amount of the powder, about that which rests on the end of a knife blade or nail file, is simply placed in a tube with atomizer bulb and blown into the nose. This is a much less wasteful method than having the patient attempt to introduce it digitally or to sniff it from a paper. Most patients are controlled with two administrations, one in the morning and one at bedtime. Some patients who do not mind the polyuria and polydipsia during the daytime use it only at night. This method is by far the least expensive method and the one which most patients prefer. It is interesting that 4 of the 8 patients mentioned by Blotner "have discontinued the use of pitressin tannate in oil because they can take pituitary intranasally and avoid injections."

INTRACTABLE INSOMNIA

To the Editor—A woman aged 66 insists that she is unable to sleep. I have tried everything I can think of or can read about without success. I know of no reason why she cannot sleep. Any advice that you can give me will be appreciated. M.D., Ontario

ANSWER—Intractable insomnia is often extremely difficult to treat. It is important, if possible, to get at the cause of the insomnia, diseases of the central nervous system are especially liable to produce insomnia, and frequently insomnia may be of psychogenic origin. It is most important, therefore, to eliminate organic causes for the insomnia by careful examination of the central nervous system and to investigate possible psychogenic origins. If anything is found, the treatment should be directed toward the disease process causing it. For the simpler types of insomnia without serious organic or functional causes, the following references may be suggested.

APPLICATION OF HEAT OR CHEMICALS TO SKIN OF PATIENT TREATED BY X-RAYS

To the Editor—A patient had intensive x-ray treatment of the front, back and outer hip-thigh regions, with considerable skin reaction. She applied dry heat to the outer aspect of her thigh (in an area treated with x-rays) for the relief of local pain. The x-ray man told her not to do that, for the heat thus locally applied over an irradiated area would much increase the local x-ray skin reaction, making it much worse. Is that true or at least enough true so that external heat should not be used?

Stuart B. Blakely, M.D., Binghamton, N. Y.

ANSWER—It is usually inadvisable to use any type of irritation, whether thermal or chemical, on the skin of a patient subjected to x-ray therapy. It is not unusual to have a skin reaction greatly exaggerated following the application of local heat even though the amount of x-rays delivered to the skin is not sufficient to cause a definite skin reaction. It is believed that a patient receiving x-ray therapy should not have heat or irritating chemicals applied to the skin.

THE EFFECTIVENESS OF TYPHOID VACCINE PREPARED BY THE U S ARMY

COLONEL GEORGE R CALLENDER
MEDICAL CORPS UNITED STATES ARMY

AND

MAJOR GEORGE F LUIPPOLD
SANITARY CORPS ARMY OF THE UNITED STATES

Siler and his co-workers included in their monograph *Immunization to Typhoid Fever*¹ a historical review of the introduction and use of typhoid vaccine in the United States Army. Briefly, typhoid vaccine was introduced on a voluntary basis by F F Russell in March 1909. In 1911 antityphoid vaccination was made compulsory for all military personnel.

From 1909 to 1916 a monovalent typhoid vaccine was used and from 1917 to 1927 inclusive the vaccine was of a triple typhoid (TAB) type containing typhoid, paratyphoid A and paratyphoid B components. In 1928 the paratyphoid B fraction was omitted, followed in 1934 by the omission of paratyphoid A. Monovalent typhoid vaccine was then used exclusively for antityphoid immunization until September 1940, at which time the paratyphoid A and B components were again added. This is the product now used for the immunization of all personnel in the Army; it contains 1,000 million typhoid bacilli and 250 million each of the paratyphoid A and B organisms per cubic centimeter.

The first typhoid culture to be used for the preparation of typhoid vaccine by the biologic laboratories of the Army Medical School was the "Rawlings" strain. This culture was isolated by British investigators from a fatal case of typhoid in 1900 and was being used by the British as a vaccine organism when Russell went abroad in 1908 to observe their methods of preparing typhoid vaccine. The "Rawlings" strain was subsequently used as the typhoid vaccine organism in the Vaccine Department of the Army Medical School from 1909 until late in 1936. During this time it had been maintained in an intermediate stage, neither rough nor typically smooth but tending toward smoothness in its cultural and antigenic characteristics.

EXPERIMENTAL STUDIES

Late in 1934 an exhaustive investigation was begun to determine the relative merits as immunizing agents of several selected strains of the typhoid organism.

Out of this investigation there emerged a strain of *Eberthella typhosa* of superior immunogenic potency. This culture had been recovered from a chronic typhoid carrier in Panama and since the first announcement of its use it has been variously referred to as "Boxill,"

Panama carrier "Panama 58" and simply "58." For the purpose of future reference it bears the official designation of *E typhosa* strain 42-A-58 of the Army Medical School culture collection.

This strain of *E typhosa* has been used by the Division of Biologic Products of the Army Medical School since late in 1936 for the preparation of typhoid vaccine and it is being used currently as the typhoid component of TAB vaccine. Briefly described it is culturally and biochemically a typical typhoid organism; colonially and serologically smooth, highly virulent for mice, and antigenically complete with a high content of Vi antigen. Before its acceptance by the Division of Biologic Products it had been subjected to every test known to us designed for determining its qualification as a vaccine organism—mouse virulence, agglutinogenic activity and immunogenic potency—and, from the standpoint of production, rate of growth, emulsifying property and stability in salt solution. Added to this were comparisons of its toxicity in human beings with that of other typhoid cultures.

Tests for its immunogenic potency were conducted with test organisms recovered from patients and carriers living in various sections of the United States. When satisfactory evidence had been secured concerning its immunogenic coverage over domestic strains of *E typhosa*, cultures from other parts of the world were sought as test organisms. Two of these foreign strains were obtained, one from China (province unknown) the other from Budapest. In both active and passive immunization tests a vaccine prepared with *E typhosa* strain 42-A-58 produced the same high degree of protection against these imported cultures as it did against the domestic variety of the typhoid organism.

Recently the question of immunogenic coverage afforded by our typhoid vaccine organism has been revived in reference to strains of *E typhosa* prevalent in the Middle East. A doubt has been expressed that our vaccine affords adequate protection against the local Middle East strains and it has been recommended that the vaccine manufactured locally be used for the immunization of the United States armed forces stationed in that area.²

Although this hypothesis is advanced from time to time it has few advocates among immunologists today. However, as a matter of interest the vaccine recommended the typhoid organisms used and some cultures from cases of disease from the area were obtained for comparative immunogenic studies. These cultures were examined for mouse virulence, antigenic content and

immunogenic potency. In all determinations our vaccine strain 42-V-58 was included as the control organism in order to detect superiority of the imported cultures over our vaccine culture, should any differences among them exist.

All cultures (those from the Middle East and strain 42-V-58) proved to be of equal virulence, they were

Rates per thousand annually for typhoid fever in the United States 1860-1942. Dotted line shows rates for all diarrheal diseases 1916-1941.

antigenically identical and they were equal in immunogenic potency when either a domestic or an imported strain of *E. typhosa* was used as the test organism. It was concluded on the basis of these experimental results that our currently used vaccine organism is quite as effective an immunogenic agent against the *E. typhosa* prevalent in the Middle East as is the vaccine organism used there and as are locally distributed strains of typhoid organisms in the Middle East.

As for the paratyphoid A and B organisms used in our 1940 type of triple typhoid vaccine, these were selected on the same bases as was the culture of *E. typhosa*. The strain of *Salmonella paratyphi* (41-N-22) was obtained from Dr. A. Felix of London and is easily the most virulent para A organism that we have found. It is culturally and biochemically typical of *S. paratyphi* antigenically complete and immunogenically superior to all other strains with which we have worked. The strain of *Salmonella schottmuelleri* (41-H-6) was first chosen from our culture collection because of its high virulence for mice and when it was shown to be an antigenically complete immunogenically active culturally and biochemically typical para B organism it was adopted to represent the B fraction of our TAB vaccine. A fuller description of these strains has recently been published by the staff of the Typhoid Research Unit.⁴

STATISTICAL STUDIES

The proof thus far presented of immunogenic coverage afforded by our vaccine organism consists of experimental evidence only. Much more significant is the statistical evidence. The actual morbidity of typhoid and paratyphoid fevers among the armed forces of the United States is shown in the chart covering the period from 1860 to 1870 and from 1896 to 1942.⁵ The rate for 1942 is an estimate since the actual

strength of troops was not available. Rates for paratyphoid were first included in the Surgeon General's Annual Report of 1912, and some paratyphoid fever occurred in most of the years following that period. In 1916, during the mobilization on the Mexican border, an epidemic of diarrheal disease, including both bacillary and amebic dysentery, occurred there together with an increase in typhoid and a more pronounced one in paratyphoid, most of which was due to *Salmonella paratyphi*. The actual number of cases for that year were typhoid 96 and paratyphoid 410, approximately 95 per cent of which was paratyphoid A.

In 1917, with an average strength for the year of 678,579, there were 297 cases of typhoid, 13 of para A and 7 of para B, a total of 317. In 1918, with an average strength of 2,518,000, there were 768 cases of typhoid, 73 of para A and 34 of para B, a total of 875. Conditions in 1918 in the battlefields of France were responsible for a considerable proportion of the cases in that year, which included a number of contact cases among those caring for the sick.

An interesting test of the efficiency of the vaccine before the addition of the A and B fractions occurred in Hawaii in 1917. A patient with typhoid in a labor camp on the watershed infected an emergency source of water used only in dry periods. This water supplied a section of the post of Schofield Barracks, the population of which was about 4,000 immunized persons, most of them soldiers, and about 800 nonimmunized, most of whom were laborers—Koreans and Japanese. Fifty-five cases occurred in the group of 4,000 and 56 in the 800 unvaccinated controls. Eleven of the 56 were considered to be contact cases. Four of the 55 patients in the immunized group died, whereas there were seven deaths among the 56 patients in the unvaccinated group. This would indicate a protection from morbidity of about 80 per cent. Another factor believed to be of importance in minimizing the incidence in the nonimmunized group is that these oriental

* Strengths on which reports were adequate

peoples seldom drink water straight, preferring tea—though their eating utensils were cleansed in unboiled water.

As a result of reports from abroad before our entry into the first world war and of the epidemic on the Mexican border in 1916, *S. paratyphi* and *S. schottmuelleri* were added to the vaccine. From 1917 through 1919, when considerable numbers of our troops were exposed in areas of relatively high endemicity, the rates continued considerably above those of the period just prior to

⁴ Longfellow, Don and Luippold, G. F. Typhoid Vaccine Studies VII. Typhoid Paratyphoid Vaccine, *Am. J. Pub. Health* 33: 561 (May) 1943.

⁵ Annual Reports of the Surgeon General of the Army, United States Treasury Department Public Health Service 1943.

the war—from 1912 to 1915 inclusive. It is interesting to note that during the period of 1917 to 1919 the rates for diarrheal disease were dropping and reached the lowest point in the history of the Army in 1919. In the United States troops were quartered in cantonments during their preparation and no extensive maneuvers were held. They were also demobilized from these same cantonments. The use of field sanitary installations for the disposal of excreta was minimal.

Because of the feeling that the para B fraction of the vaccine caused an undue amount of reaction and because of the very small number of cases of paratyphoid B which were occurring in the countries where troops were stationed this fraction was removed in 1928, and this was followed in 1934 by the removal of the para A fraction. The sharp rise in the typhoid rate in 1931 was due to 22 cases occurring in one organization which used unpasteurized and infected milk while on a maneuver. The number of cases of paratyphoid as well as typhoid were insignificant between 1919 and the present time with the exception of the 1931 group. The removal of para A and para B fractions does not appear to have influenced the rates for typhoid and paratyphoid fevers although the general level of the incidence of diarrheal diseases increased appreciably in 1930 from about 12 to 20 per thousand and did not recede in subsequent years.

With the mobilization of the emergency period, typhoid rates show no significant change in 1940, during which there was a considerable amount of activity of troops in the field utilizing improvised installations for the disposal of human wastes. But during this period there was a very distinct advance in the rates for diarrheal diseases including bacillary and amebic dysentery, diarrhea with cause not specified, gastritis and enteritis and colitis and enteritis. The combined rates were 17.74 for 1938, 24.79 for 1939, 37.09 for 1940, 49.89 for 1941.

Increase in the diarrheal diseases is usually accompanied by increase in typhoid. This is especially true in armies operating under field conditions. The diarrheal diseases usually occur in the greater numbers though typhoid has the highest fatality rate. The accompanying table compares typhoid and paratyphoid with diarrheal diseases for four war periods.

The result of vaccination in World War I as compared with previous wars is evident, though the diarrheal rates were only about half those of the prewar period exclusive of 1916. Rates for 1940 and 1941 only are calculable, those for 1942 being estimated because records of the strength of the Army are not available. Typhoid and paratyphoid fever rates in these years are insignificant, and this in the presence of rising rates for the diarrheal diseases. This picture can be interpreted only as definite evidence of the efficiency of the present vaccine.

SUMMARY AND CONCLUSIONS

Following the compulsory use of typhoid vaccine in the U. S. Army in 1911 morbidity rates for typhoid and paratyphoid fevers dropped from about 2.5 per thousand annually in 1910 to below 0.2 for 1913-1915 inclusive, the Army having few troop maneuvers during this period.

In 1916 an epidemic condition of typhoid and paratyphoid fevers and diarrheal disease in the Army operating in the field resulted in rates for typhoid and paratyphoid fevers approximating those of 1910, most of the increase being due to paratyphoid A. No para-

typhoid organisms were included in the vaccine of that period.

The rates for typhoid and paratyphoid remained well above the peacetime level of 1913-1915 during the three years of World War I yet were significantly below the peacetime level of the prewar period—about 3 to 4 as compared to 0.3 to 0.4.

During the peace period of 1919 to 1939 rates were in the range of 0.01 to 0.08 with the exception of the food borne outbreak of 22 cases in 1931.

Thus far, rates for typhoid and paratyphoid fevers for the mobilization years 1940-1942 are insignificant, and this in the face of a rise in the rates for diarrheal diseases to higher levels than the period preceding World War I.

With this evidence it appears reasonable to conclude that the World War II (1940 type) triple typhoid vaccine is considerably superior in effectiveness to the TAB product employed during World War I.

VISCOSE TUBING FOR TRANSFUSIONS

A REACTION REDUCING MATERIAL AND A
SUBSTITUTE FOR RUBBER

HENRY NAFTULIN

A. M. WOLF, M.D.

AND

S. O. LEVINSON, M.D.

CHICAGO

With the introduction of sodium citrate as an anti-coagulant by Lewisohn¹ and the development of the modern technique of blood transfusion this procedure became routine and easily performed. However under the most careful conditions a small incidence of untoward reactions, principally chills and fever, has remained a disturbing factor. Untoward reactions of this kind may be divided into two groups: intrinsic reactions arising from the infused blood, and extrinsic reactions arising from causes other than the blood.

This paper deals with extrinsic reactions. It has been amply demonstrated that the febrile reaction is largely due to the inadvertent injection of foreign material into the blood stream.² Many theories have been advanced in an attempt to explain the febrile reaction that is occasionally associated with the whole blood infusion and for that matter, with intravenous infusions in general. Able investigators working along this line have shown that the reactions arise principally from three sources: pyrogenic substances in distilled water,³ impure chemicals used for preparing solutions,⁴ and improperly or inadequately cleansed equipment.⁵

Even with constant vigilance and unrelenting care in the preparation of the material used in the drawing and the administration of citrated blood the incidence of febrile reactions is still from 1 to 10 per cent or higher.

In an effort to reduce the number of reactions following the administration of citrated blood we first

eliminated the character of solutions and the manner of cleansing glass and metal parts as factors in the febrile reaction. The solutions in use at the Michael Reese Hospital transfusion department are commercially prepared and proved pyrogen free on test and the glass and the metal parts are relatively easy to clean and inspect. However, a small incidence of reactions

Fig. 1—A 3-inch length of rubber tubing is slipped onto the Viscose tubing.

remained and our suspicion centered on the rubber tubing because of the difficulties involved in the cleansing of tubing. New rubber tubing is covered with silt and other impurities which must be removed to render it pyrogen free. Rubber tubing which has been used for a blood or a plasma transfusion must be so thoroughly cleansed that there is complete removal of all residual protein matter from the lumen. One can never be certain that this has been accomplished.

Our method of preparing new and used rubber tubing is described in another publication.⁶ This method of cleansing is diastatic treatment to the rubber but was employed to reduce the possibility of febrile reactions. The effectiveness of this cleansing procedure was shown in a study by Zimmerman, Strauss and Laufman.⁷ Five consecutive series of five hundred transfusions each were analyzed and showed progressive reduction in the incidence of transfusion reactions as the technique of the cleansing of rubber tubing and other equipment for intravenous injections was improved. The total incidence of pyrogenic reactions in the final series was 2.2 per cent, compared with 5.2 per cent in an earlier series.

The diastatic cleansing of rubber eventually destroys its original elasticity. The original elasticity is what

Fig. 2—After moistening the Viscose tubing is gently stretched with a hemostat.

makes rubber desirable for use in intravenous administration work. Once the tubing begins to deteriorate fissures develop on the inside, and in this condition it can no longer be satisfactorily cleansed by any known procedure. It is hazardous to use old tubing for the administration of plasma, serum or blood because the protein material cannot be completely removed. The

residual protein material will then be subjected to autoclaving in sterilizing the administration set, and the coagulated protein even in minute amounts can cause severe reactions when a subsequent transfusion washes it into the blood stream. Old tubing may be used with relative safety when it is restricted solely to the administration of dextrose and saline solution and when protein material does not come in contact with it.

With these inherent defects of rubber tubing in mind, we sought a substitute. The regular Viscose tubing described by Hartman⁸ was found by us to be fragile, difficult to handle and rather permeable to fluids. However, in our experience the heavy walled Viscose tubing has been free from these objections. The heavy walled tubing is far sturdier. The manufacturer impregnates the material with glycerin, which acts as a hygroscopic agent. The moisture content determines the suppleness of the Viscose tubing. Refrigerator storage is desirable for partially used rolls. The tubing is supplied in lengths of 1,500 feet on spools, wrapped in wax paper and at a cost so low that "one time use"

Fig. 3—The expanded Viscose tubing is slipped onto the needle glass adapter 1/4 inch.

Fig. 4—The rubber tubing is slipped onto the joint and the clamp placed in position.

and discarding come to less than the cost of rubber considering the time labor and material used in maintaining rubber tubing. The drying effect from autoclaving can be minimized by making a compact package of each length of tubing to be sterilized and placing it within a glass tube measuring 25 by 100 mm. The glass tube inhibits vaporization of the moisture in the Viscose tubing during sterilization. In contrast to its brittleness when dry, Viscose tubing is quite pliable when wet and permits the required manipulation.

It was important to know whether the Viscose tubing was pyrogen free, impermeable to pyrogens and impermeable to bacteria.

EXPERIMENTAL STUDIES

To determine whether the Viscose tubing was pyrogen free, 6-inch lengths were cut of every hundred feet from two rolls of Viscose tubing of 1,500 feet each. The specimens were cut into small pieces with sterile scissors and boiled in 200 cc. of pyrogen-free distilled water for fifteen minutes. The water was filtered through filter paper, made isotonic with sodium chloride and subjected to a pyrogen test.⁹ The pyrogen test was negative.

To ascertain whether pyrogens could diffuse through the wall of the Viscose tubing the following tests were performed:

crystalline pyrogen¹⁰ was used. The intravenous injection of 0.08 cc. (0.016 mg) of this pyrogen into a dog weighing 13 kg caused a rise in rectal temperature of 1.9 degrees F in two hours. To determine the effect of this pyrogen on rabbits approximately 0.05 cc of a 1:400 dilution of the pyrogen was injected into each of 5 rabbits. All the rabbits showed a positive response; the average rise in temperature was 2.5 degrees F. Then 10 cc (0.2 mg) of the concentrated pyrogen was placed in a length of Viscose tubing, and the tubing was suspended in 400 cc of sterile non-pyrogenic isotonic solution of sodium chloride. Another flask containing 400 cc of the same lot of saline solution served as a control. At the end of two hours at room temperature the Viscose tubing containing the pyrogen was removed and the saline solution in each flask was subjected to a pyrogen test.¹¹ The saline solution in both flasks proved pyrogen free.

To determine whether bacteria could diffuse through Viscose tubing, the following test was performed. A diphtheroid isolated from contaminated human serum was inoculated in 15 cc of Brewer's medium; the medium was then placed in a length of Viscose tubing and the tubing suspended in 400 cc of sterile Brewer's medium. At the end of three weeks incubation at 37.5 C the medium surrounding the tubing was clear and sterile whereas the medium in the Viscose tubing was turbid indicating that bacterial growth was present in the tubing and that it had not penetrated through the tubing wall.

Fig 5—An airtight testing system uncovers leak sections of tubing. After testing suction is applied to return the tubing to its original flat shape.

TECHNIC OF ASSEMBLY

The following technic has been developed for the use of Viscose tubing in assembling administration equipment.

- 1 Cut suitable lengths of tubing. Avoid sharp bends if the material is brittle.
- 2 Slip a 3 inch piece of rubber tubing over one end of the Viscose tubing moving it down the Viscose tubing so that the terminal end of the Viscose tubing is exposed 2 inches (fig 1).
- 3 Dip the exposed end of the Viscose tubing into pyrogen free distilled water for twenty to thirty seconds to permit wetting.
- 4 Insert a small hemostat into the lumen and enlarge the lumen by gentle spreading of the blades of the hemostat (fig 2).
- 5 Moisten the end of a glass observation needle adapter in the distilled water; shake off excess water and slip 3/4 inch of the expanded tubing over the glass fitting (fig 3).
- 6 Allow the tubing to dry. This takes about ten minutes. The tubing will shrink and grip the glass. No adhesives are necessary.

¹⁰ B12 2" no 2 supplied through the courtesy of Dr. Heinrich Nechele, director of the department of gastroenteral research of the Michael Reese Hospital.

7 Slide the rubber tubing down over the glass part. Moistening the Viscose tubing and glass will facilitate this procedure. The rubber tubing acts as a guard at the junction of the Viscose tubing and the glass part; it also serves as a site for the metal clamp used for regulating the flow (fig 4).

8 Each section of tubing must be examined for pinhole leaks. This is done by clamping off the free end of the Viscose tubing and inflating the tubing with a pressure bulb on a

Fig 6—The Viscose tubing is folded on itself into a small package which can be slipped into a test tube. The other end of the tubing is ready for attachment to the second glass adapter.

manometer until the gage shows a pressure of 250 mm of mercury. Close off the source of pressure and observe the gage. The reading should remain stationary. A rapid fall means that there is a leak in that section of tubing and that it should be discarded. A multiple testing manometer can be constructed simply (fig 5).

9 With a suction bulb completely evacuate the tubing until it is flat.

10 Fold the Viscose tubing on itself until it is a compact package about 2 inches long with the terminal end exposed about 3 inches. Wrap a band of paper around the tubing and fix it with a piece of Scotch tape. This will prevent the Viscose tubing from buckling in the autoclave (fig 6).

11 Slip a 1 1/2 inch piece of rubber tubing over the remaining free end of the Viscose tubing until 1 1/2 inches of Viscose tubing is exposed. Dip the end in the distilled water; expand and slip onto the glass filter chamber. Allow the Viscose tubing to dry and slip the rubber guard onto the glass.

12 Complete assembly by connecting the filter to a glass Y tube (7 mm) using a 2 inch piece of rubber tubing (1/8 by 1/4). Slip a 3 inch piece of rubber tubing (1/4 by 3/16) onto each

Fig 7—The assembly is completed and ready for wrapping and sterilization. Immediately before use the Viscose tubing will be soaked in water in the test tube to restore its suppleness.

end of the Y tube. Insert a glass bottle adapter in the free end of the rubber tubing and cover each adapter with unbleached muslin. Adjust shut-off clamps. Slip a glass tube 25 by 100 mm over the Viscose tubing. This glass tube will prevent excessive drying of the Viscose tubing in the autoclave (fig 7).

13 Wrap in two layers of gauze and then in flannel for sterilization and sterilize at 15 pounds pressure for twenty minutes.

14 When the assembly is ready for use proceed as follows:

(a) Unwrap the sterile covering; remove the glass tube; remove the binding around the Viscose tubing. Aseptic technique is not necessary in handling the tubing.

(b) Fill the test tube three-fourths full with water (cold tap water may be used) and completely immerse the Viscose tubing in the water for one minute. The tubing will become soft and pliable.

(c) Close the shut-off clamp near the bottle adapter. Insert the adapter into the bottle and suspend the bottle on a rack at the proper height.

(d) The Viscose tubing should now be extended to its entire length. Avoid twisting the tubing.

(e) Open the shut-off clamp and allow the tubing to fill. Air bubbles can easily be seen and removed. Close the shut-off clamp near the needle adapter, insert the needle into the vein, then open the shut-off clamp to allow fluids to run. The flow of fluids must be regulated by the clamp near the needle adapter. This will prevent the tubing from collapsing.

15 After one time use the Viscose tubing is discarded.

16 The foregoing technique is used in combination with rubber tubing. The rubber tubing is used for a few inches of connection and the Viscose tubing for sections requiring the bulk of tubing. Only new rubber tubing is used, and it is discarded after one time use.

CLINICAL STUDIES

In order to determine the value of "one time use" Viscose tubing in reducing reactions in blood transfusions, we studied 600 transfusions, alternating rubber

TABLE 1—Incidence of Pyrogenic Reactions with Rubber Tubing and with Viscose Tubing

	Transfusions	Pyrogenic Reactions			Total
		Major	Minor	Allergic	
Rubber tubing	300	2 (0.67%)	5 (1.7%)	1 (0.33%)	8 (2.7%)
Viscose tubing	300	0 (0.00%)	0 (0.00%)	2 (0.67%)	2 (0.67%)

TABLE 2—Analysis of Reactions with Viscose Tubing

Transfusions Made with Viscose Tubing	Pyrogenic Reactions			Total
	Major	Minor	Allergic	
1,137	1 (0.09%)	4 (0.3%)	3 (0.25%)	8 (0.64%)

tubing and Viscose tubing. The results are recorded in table 1. This table shows a striking reduction in the number of pyrogenic reactions with Viscose tubing.

We classify as major a pyrogenic reaction in which there is a chill and a rise in temperature of 2 degrees or more above the pretransfusion level. If the elevation of temperature is less than 2 degrees and there is no chill or a mild one, the reaction is considered minor.

All infusions of whole blood, plasma and serum at this institution are now administered through Viscose tubing. The total reaction rate for all transfusions administered with Viscose tubing is recorded in table 2. The table shows a total of five pyrogenic reactions. The one major reaction occurred in a woman (group O) who received 500 cc of citrated fresh blood. There was no untoward reaction at the time of the transfusion, and her temperature remained normal throughout the day. The following day, twenty-four hours after the transfusion, the patient complained of a chilly sensation and her temperature rose to 103.8 F. Forty-eight hours after the transfusion her temperature fell to 98.6 F.

The four minor pyrogenic reactions all occurred in a single patient, a 12 year old Negro girl (group A,

Rh positive) suffering from sickle cell anemia. She had previously been in the hospital in July 1942 and at that time received six transfusions through rubber tubing. After three of these transfusions she experienced an immediate chill and a rise in temperature ranging from 1 to 2 degrees F. She was readmitted to the hospital in April 1943 and subsequently received four transfusions through Viscose tubing. A rise in temperature of 1 degree F without chills occurred from three to six hours after each transfusion.

In 1941 Zimmerman and his associates⁷ noted that febrile patients and patients suffering from leukemia showed a significantly higher incidence of untoward reactions than afebrile and surgical patients receiving citrated blood. He pointed out that patients suffering from septic diseases are particularly sensitive to minute and otherwise innocuous amounts of pyrogenic material.

An opportunity to use rubber tubing and Viscose tubing alternately in the same patient presented itself in 3 instances (2 of leukemia and 1 of ulcerative colitis).

CASE 1—A girl aged 14 years (group A, Rh positive), suffering from ulcerative colitis, received fourteen transfusions of citrated blood of 250 cc each over a period of four months. All the blood was homologous and was never over 72 hours old. Seven transfusions were administered through rubber tubing and seven through Viscose tubing. Three reactions developed following transfusions through rubber tubing. One was a pyrogenic type with a chill and a rise in temperature from 99.0 to 100.0 F without chills. Following the transfusions with Viscose tubing there were no febrile reactions but there was one allergic reaction.

CASE 2—A J, a woman aged 43 (group O), suffering from monocytic leukemia, received fifteen transfusions of citrated blood of 500 cc each over a period of eight weeks. All bloods given were less than seventy-two hours old. Eight transfusions were administered through rubber tubing and seven through Viscose tubing. Following the transfusions with rubber tubing two major pyrogenic reactions developed. The seven transfusions administered with Viscose tubing were uneventful.

CASE 3—C M, a man aged 63 (group O), suffering from chronic myelogenous leukemia, received fifteen transfusions at another hospital and had a history of several pyrogenic reactions. Three subsequent transfusions administered through Viscose tubing were uneventful.

SUMMARY

The cleansing of rubber tubing to be used for intravenous administration of blood or blood protein is difficult. Incomplete cleansing of rubber tubing is believed to be a major cause of pyrogenic reactions.

Heavy walled Viscose tubing is sturdy, pyrogen free, impermeable to pyrogens, impermeable to bacteria and quite practical for one time use.

In a total of 1,137 blood transfusions given through Viscose tubing the incidence of pyrogenic reactions was 0.64 per cent. This is a material decrease from the reaction rate encountered with rubber tubing.

Cardiovascular Signs of Emotion—The heart and the gastrointestinal tract are the most sensitive recorders of a disturbed emotional state. The intimate connections between the autonomic nervous system and the heart are so close as almost to justify the statement that cardiac rhythm and rate are a measure of the activity of the state of tension in the sympathetic and the parasympathetic systems.—Krames, Samuel H. Therapy of the Neuroses and Psychoses, Philadelphia, I. C. Febiger, 1943.

SULFAMERAZINE

A CLINICAL STUDY OF ITS PHARMACODYNAMICS
THERAPEUTIC VALUE AND TOXICITY

PAUL Q. HAGEMAN, MD

SIDNEY S. SOBIN, MD

AND

ROY E. AHRENS, MD

ST. LOUIS

As a result of the rather frequent occurrence of crystalluria and hematuria following the use of sulfathiazole and sulfadiazine an effort has been made to find a sulfonamide derivative of comparable therapeutic potency with less tendency to produce crystals in the urinary tract. This problem is of special importance to our armed forces stationed in warm climates where it is exceedingly difficult to maintain a satisfactory urinary output.

Sulfamerazine (2-sulfamylamido-4-methylpyrimidine) has been investigated because of its greater solubility as compared to other pyrimidine derivatives.¹ Welch and his co-workers² found that sulfamerazine and its

Chart 1—Absorption curve following 4 Gm of sulfamerazine given orally with maintenance dose of 1 Gm every eight hours. Blood levels are expressed as mg % of free sulfamerazine. Curve at top maximum at bottom minimum in center average.

satisfactory blood levels might be attained with smaller doses of sulfamerazine and that the interval between doses might be lengthened. During the past four months 103 patients have been treated with sulfamerazine at the Barnes Hospital and the St. Louis City Isolation Hospital. The therapeutic results and toxic reactions observed constitute the subject of this paper.

From the Department of Medicine, Washington University School of Medicine.

This study was carried out at the suggestion of the Chemotherapy Committee of the National Research Council.

The essential part of the work was done by the staffs of Barnes Hospital and the St. Louis City Isolation Hospital.

PROCEDURE

All patients were accepted for treatment provided other sulfonamides had not been previously administered during the current illness. In general the drug was administered as follows:

An initial dose of 4 Gm was given (orally when feasible) and maintenance doses of 1 Gm every eight hours were given thereafter. For severely ill patients this dosage scheme was modified and initial doses up to 8 Gm and maintenance doses of 2 Gm every eight hours were often given. In addition, if blood concentrations did not attain desired levels, supplementary doses were occasionally administered. Alkalis were not given to any patient. It was planned to force fluids to 3000 cc in twenty-four hours in all cases in an effort to obtain a urinary output of 1,000 cc or more in twenty-four hours. Because of the shortage of hospital personnel it was not possible to control the fluid intake adequately in every case, particularly during epidemic periods and in certain instances the fluid intake fell below the desired level. Blood concentrations were measured at least every twenty-four hours at a time just preceding the eight hour maintenance dose. Determinations of the sulfamerazine concentration were done by the method of Bratton and Marshall.⁶ All figures quoted are values for free sulfamerazine in whole blood. Urinalyses were performed daily during treatment, the microscopic examination being done as soon as possible after the patient voided. In some instances specimens remained at room temperature for one or two hours before being examined. Red blood cell counts, hemoglobin determinations and white blood cell counts were made at least every three days during treatment.

Chart 2—Average of blood and spinal fluid free sulfamerazine levels in 10 cases of meningococcal meningitis. Curve at top blood at bottom cerebro spinal fluid.

Chart 3—Diffusion of free sulfamerazine into uninfected spinal fluid following oral administration of 4 Gm of sulfamerazine. Curve at top blood at bottom cerebro spinal fluid. The 4 and 36 hour figures are the average of two sets of observations. Other values represent individual instances from different patients.

Culture mediums employed were beef or horse infusion broth and agar with 1 per cent Bacto-peptone, 1 per cent dextrose and 5 mg of para-aminobenzoic acid per hundred cubic centimeters. Spinal fluid cultures were

6. Bratton, A. C., and Marshall, E. H. A New Colorimetric Method for the Determination of Sulfanilamide Derivatives. *J. Biol. Chem.* 62, 1, 1945.

made on beef or horse infusion blood agar slants. Cultures for meningococci were grown in 10 per cent carbon dioxide. In many instances additional samples of spinal fluid were inoculated on the chorioallantoic membrane of the chick embryo.⁷

PHARMACODYNAMICS

Absorption of the drug was followed closely in the first twelve patients treated (chart 1). The resulting

tration of the drug to patients without meningitis who had lumbar punctures for various reasons. These are plotted in chart 3 and suggest that a considerable lag occurs in the diffusion of the drug into the uninfected spinal fluid. In several instances simultaneous blood and pleural fluid concentrations were observed to show approximately the same levels in the fluid and the blood (examples: blood 64, pleural fluid 64, blood 67, pleural fluid 68, blood 63, pleural fluid 79).

curves are similar to those obtained by Welch² and by Goodwin.⁸ Both rapid absorption and maintenance of high blood concentrations, with the drug administered every eight hours, are well demonstrated.

During the course of the study the diffusion of sulfamerazine into the spinal fluid was observed (chart 2) care being taken to use 1 per cent metycaine⁸ as a local anesthetic. In 19 cases of meningitis the spinal fluid concentrations averaged 49 per cent of the blood concentrations during the period of treatment. A few observations have been made on the relative concentrations of blood and spinal fluid shortly after adminis-

THERAPEUTIC RESULTS

(a) *Meningococcal Infections*—Thirty-seven patients with meningococcal meningitis were treated as outlined in table 1.⁹ The therapeutic results were, on the whole, satisfactory. Most of the patients improved rapidly under treatment and all but 5 recovered. There were 3 pregnant women (6 I, 31 I, 42 I) who recovered without apparent harm to the fetus. A single case

9 Blood and spinal fluid levels are charted as follows: (1) the value attained twenty-four hours after the onset of treatment; (2) the maximum level reached; and (3) the average level observed during the period of therapy. Case numbers are accompanied by the letters I and F indicating the hospital in which the patient was treated: I = City Isolation Hospital or Barnes Hospital.

7 Through the courtesy of Dr. Russell Blattner. To be published.
8 Gammar (2-methylpiperidino) propyl Benzoate Hydrochloride, Lilly.

(55 B) was complicated by diabetic acidosis and the patient survived. In one instance (21 I) a complicating iritis subsided without a residual lesion. A man aged 74 (24 I) developed the disease on the second postoperative day following a transurethral prostatic resection and under sulfamerazine therapy his recovery was uneventful.

On a number of occasions a low grade fever persisted for several days after the patient seemed to have

(b) *Pneumococcal Infections*—Seventeen patients with pneumococcal infection were treated as outlined in table 2. The results were uniformly good in the pneumococcal infections but there were only 2 patients with bacteremia. Patient 17 I with meningitis and bacteremia died thirteen hours after being admitted to the hospital.

(c) *Streptococcal Infections*—Fifteen patients with streptococcal infection were included in the present

otherwise recovered completely (examples 15 I 16 I). Cultures of blood or spinal fluid remained positive for several days in a few instances (9 I 15 I 25 I 34 I 35 I). The only possible residual lesion was observed in patient 55 B who has an increased left ankle jerk and is still under observation.

Five patients in the group (25 I 27 I 32 I 36 I and 41 B) all of whom were elderly with complicating medical conditions such as hypertension hemiplegia and kidney insufficiency failed to survive. The case fatality rate for the group of 37 patients was 13.5 per cent.

series (table 3). Although these were not severe infections (except 45 B) the response to treatment was satisfactory. In 1 instance (33 B) an abscess formed which contained sterile thin pus. Patient 45 B had severe uncontrolled diabetes with advanced gangrene of one foot. Blood cultures contained 8 to 12 organisms per cubic centimeter at the onset of treatment and subsequent cultures showed no growth. The patient died on the third day of treatment.

(d) *Urinary Tract Infections*—Four patients with urinary tract infections were treated as outlined in

table 1. Results were uniformly satisfactory, however, none of the patients had bacteremia.

(c) *Miscellaneous Infections*—Thirty patients with miscellaneous diseases including gonococcal and staphylococcal infections also were treated and the results

Drug fever with morbilliform rash was observed twice (28 I, 34 I) (19 per cent). The rash was similar to that seen with other sulfonamides.

Neuropathologic changes, agranulocytosis, anemia, nausea and vomiting were not observed in this series.

TOXICITY

Drug fever was noted in 6 instances (1 B, 27 B, 53 B, 55 B, 58 B, 48 I), an incidence of 5.8 per cent. This reaction was not unlike that observed with other sulfonamides as to severity, time of appearance and response to withdrawal of drug.

Although animal experiments² had not shown notable neuropathologic changes, neurologic symptoms and signs were carefully watched for because of the experience reported with sulfamethylthiazole a similar methyl derivative.

Crystalluria without hematuria was noted in 7 cases (4 B, 6 B, 19 B, 2 I, 4 I, 23 I, 37 I), an incidence of 6.8 per cent. None of the patients complained of symp-

toms, and the crystals could be seen only microscopically. Eight other patients showed crystalluria in urine specimens that were exposed to room temperature for one to two hours, but these results were discarded when fresh urines were found to be free of crystals. In every instance in which fresh urines were not checked to confirm the presence of crystalluria, the case was included as one showing crystalluria. The mere fact that crystals often appeared at room temperature soon after voiding suggests that the urine approaches saturation with sulfamerazine and its acetyl derivatives. Attempts to relate the presence of crystals to the blood concentration failed to reveal a correlation.

One patient (25 I, table 1) had no crystals or red blood cells in daily urine samples but at autopsy was found to have concretions of sulfonamide crystals in

parable to that obtained with a larger fluid intake in a hot climate.

Hematuria was observed in 9 instances (87 per cent) (table 5). In 3 of the 9 cases the hematuria was grossly visible and in the others the red blood cells varied from "many" to "occasional" (47 I) per high power field in the centrifuged specimen. Crystalluria was observed at some time during treatment in 3 of the 9. Attempts to correlate the occurrence of hematuria with blood levels have shown no apparent relationship. Four of the 9 patients had petechiae in the skin.

Patient 29 I was menstruating at the time hematuria was reported. Catheterized specimens contained red blood cells, but the possibility of menstrual contamination is not excluded since a two glass technic was

|| Duration of hematuria

both ureters. Since the patient had received sulapyridine following cessation of sulfamerazine treatment the identity of the crystals was open to question. Samples were sent to Sharpe and Dohme¹⁰ and were identified as acetyl-sulfamerazine. The daily fluid intake averaged 1,800 + cc and the urinary output 850 + cc during the period of sulfamerazine treatment. Blood nonprotein nitrogen was not measured at any time, as urinary complications were not suspected. Urinary suppression was not noted terminally, but the output was not accurately known because of urinary incontinence. This patient received large doses of sulfamerazine averaging 8 Gm in twenty-four hours for fifteen days and the blood concentration reached 29 mg per hundred cubic centimeters on one occasion. It is felt that the crystalline deposits were due to an inadequate intake of fluid but the urinary output might be quite com-

not employed. It is of interest that patient 36 B had a bloody stool on the day hematuria was reported; no subsequent episodes of hemorrhage occurred.

None of the patients developed nitrogen retention, urinary suppression or other evidence of kidney impairment. Symptoms cleared promptly with every patient on cessation of therapy.

COMMENT AND SUMMARY

Experience accumulated in the treatment of 103 patients has demonstrated that sulfamerazine is rapidly absorbed from the gastrointestinal tract and is rather slowly excreted by the kidney. Adequate drug levels can be maintained by doses administered at eight hour intervals. The drug readily diffuses into pleural fluid in concentrations approximating that of the blood and into spinal fluid in concentrations approaching 50 per cent of that in the blood. Patients tolerate sulfamerazine well side effect being few in number.

10 Through courtesy of Dr. Earl L. Burdidge Jr.

Therapeutic results in meningococcic, pneumococcic, streptococcic and colon bacillus infections were satisfactory and compared favorably with those reported for sulfadiazine.

The toxicity of sulfamerazine has been critically evaluated. The incidence of hypersensitivity (drug fever and rashes) seems to be about the same as that observed with other sulfonamide derivatives. Evidence of kidney and urinary tract complications was more frequent than was anticipated from pharmacologic data and preliminary tests in experimental animals. Crystalluria without hematuria was observed in 68 per cent of the series. This complication was benign in all instances. One patient without hematuria or crystalluria had concretions of acetylsulfamerazine in both ureters at autopsy. This patient had received large amounts of the drug and his fluid intake was sub-optimal. It is probable that the incidence of crystalluria would have been lower if more fluids had been administered or if the urine had been alkalinized.

Hematuria was noted in 87 per cent of the patients. In consideration of the incidence of hematuria it should be borne in mind that in all but 1 (possibly 2) instances this complication occurred in patients with meningococcic meningitis who received particularly large doses of the drug because of the serious nature of the infection. The occurrence of hematuria could not, however, be related to the blood concentration of the drug. Certain of the patients received a lower fluid intake than was planned. The average fluid intake for the preceding days in 2 of the 3 cases of gross hematuria was only 1,730 and 1,875 cc respectively. These cases may give some indication of the results to be expected in tropical climates. Since 4 of the 9 patients had hemorrhagic skin manifestations, the suggestion is made that hematuria resulted in certain instances from similar lesions in the kidney. It may be noted further that hematuria was sought for by daily examinations of urinary sediment and that in 6 of the 9 cases the hematuria was discovered only by microscopic examination. It is important to point out also that the hematuria subsided promptly in each case without any evidence of embarrassment to kidney function.

The chief reason for clinical trial of sulfamerazine at this time was the possibility that it might produce fewer and less severe urinary complications than sulfadiazine in warm climates under military conditions. Our experience confirms the previous reports that less of the drug is needed for comparable blood levels, but no conclusion can be drawn as to whether urinary complications occurred more or less often than would have been the case had sulfadiazine been used on the same patients. In certain of these cases circumstances under which the drug was administered were such as to offer an excellent opportunity for urinary complications, and it seems likely that the accumulated results of other observers may indicate that sulfamerazine produces fewer renal complications than sulfathiazole and sulfadiazine.

Expansion of Intestinal Gas—In an ascent to 38,389 feet, one volume of gas originally in the intestinal tract at sea level now occupies 5 volumes. This expansion of gas causes distention and abdominal discomfort in the aviator ascending to such altitudes and may cause respiratory and circulatory distress if the expansion of the gas forces the diaphragm to push up on the heart and lungs—Gemmell, Chalmers L. *Physiology in Aviation*, Springfield, Ill., Charles C Thomas, Publisher 1943.

THE CHEMOTHERAPY OF INTRACRANIAL INFECTIONS

III THE TREATMENT OF EXPERIMENTAL STAPHYLOCOCCIC MENINGITIS WITH INTRATHECAL ADMINISTRATION OF PENICILLIN

COBB PILCHER, MD
AND
WILLIAM F. MEACHAM, MD
NASHVILLE, TENN.

The great promise of penicillin as an antibacterial agent has recently received wide publicity, even in the lay press. The discovery of its antibacterial activity by Fleming¹ in 1929 and the outstanding investigations of Chain, Florey and their co-workers² beginning in 1940 have been reviewed by Hobby, Meyer, Dawson and Chaffee³ (who also contributed valuable observations of their own). A recent summary of early clinical observations in Great Britain has been published by the Floreys⁴ and extensive investigation of the use of penicillin is being carried on in this country⁵.

Chart 1—Effects of a single intravenous injection of penicillin in staphylococcic meningitis.

The experimental study to be reported herein was undertaken as one of a series of investigations of the treatment of infections of the central nervous system and its coverings⁶. This report will be limited to consideration of the effects of penicillin in experimental staphylococcic meningitis.

Read before the Harvey Cushing Society, New York, May 8, 1941.
From the Department of Surgery, Vanderbilt University School of Medicine.

The penicillin was furnished by E. R. Squibb and Sons, New Brunswick, N. J., through the kindness of Dr. George Harrop.

The work described in this paper was done under a contract recommended by the Committee on Medical Research, between the Office of Scientific Research and Development and the Vanderbilt University.

The Clinical and Pathologic Effects of the Intracranial Injection of Sulfanilamide, Sulfathiazole and Sulfadiazine in *Necrotic* to be published.

METHODS AND RESULTS

Dogs weighing 7 to 10 Kg were employed in all experiments. Meningitis was produced by injection of 0.1 cc of a saline suspension of a strain of hemolytic *Staphylococcus aureus* into the cisterna magna. This

volume contained approximately 400 million organisms. Filtrates of cultures of this organism showed no evidence of toxin formation.

In order to insure that the virulence of the organism should be as nearly constant as possible in successive groups of experiments, the following method of preparation was employed. The organism selected was "passed through" the spinal fluids of a number of dogs until it consistently produced a fulminating fatal meningitis.

It was then cultured in a large volume of beef infusion broth containing 10 per cent human plasma for sixteen hours. Finally, small quantities of this culture were sealed in a large number of small glass ampules. The latter were placed in a large container of alcohol, which in turn was kept packed in solidified carbon dioxide in a freezing chamber. The contents of one of these ampules were used for each group of experiments. Each group consisted of 12 dogs. In some groups 6 were treated and 6 served as controls. In others 4 had treatment at one time, 4 at another and 4 served as untreated controls.

Necropsy was performed and microscopic studies were made in most of the experiments, but there were

Chart 2—Effects of intravenous penicillin therapy in staphylococcal meningitis

Intravenous Therapy—When the first of these studies was begun the amount of penicillin available was extremely small. For this reason the effects of a single large (2,500-3,000 Florey units) intravenous dose given either one hour or three hours after injection of staphylococci were determined (chart 1). It is sufficient to say of the results that, although there was considerable variation in different groups, no significant beneficial effect of the treatment was observed.

When more penicillin became available an additional series of experiments was carried out in which intravenous therapy was begun before injection of staphylococci and continued in equally spaced doses of 500 units five times daily as shown in chart 2. Of the 24 dogs 3 treated and 2 control animals recovered. Seven treated animals, as compared with 10 controls failed to survive eight hours.

Intrathecal Therapy—When these experiments were begun there was no published report of the intrathecal injection of penicillin. Since intravenous treatment of staphylococcal meningitis had not proved effective, it seemed advisable to determine the value of intrathecal therapy. First, however, the effects of intracisternal injections of penicillin in normal dogs were studied.

Chart 4—The spinal fluid cell count on normal dogs following repeated injections of 50 units of penicillin

Such injections produced transitory meningeal reactions whose intensity was roughly proportional to the dose (chart 3). Repeated doses at twenty-four hour intervals increased the severity of the reactions only slightly (chart 4). No significant neurologic or systemic phenomena were observed. The animals were alert, took food and fluids normally and had no significant febrile reactions.

On the basis of these observations it was decided to use an intrathecal dosage of 50 Florey units administered once daily.⁵ Treatment was begun either one hour before or one hour after injection of staphylococci (chart 5).

In every one of the four series the mortality rate was much lower and the number of animals which either recovered or lived more than twenty-four hours was far higher in the treated than in the control groups.

In the forty-seven experiments only 1 of 15 control dogs (6 2/3 per cent) recovered whereas thirteen of the 32 treated animals (40.6 per cent) recovered (chart 6).

The number of animals which recovered was greater in the groups in which treatment was begun after injection.

⁵ Through the assistance of the Committee on Medical Research of the Office of Scientific Research and Development.

⁶ Later observations to be published elsewhere have shown that a larger and more frequent intrathecal dose is well tolerated and we regret that this was not employed in these experiments.

Chart 5—The spinal fluid cell count following a single intrathecal injection of penicillin

no significant findings other than the varying degrees of meningeal inflammation which would be expected.

For statistical evaluation of results in this type of experiment only two criteria are of real significance: namely, mortality rate and duration of life. These two factors are shown in the accompanying charts.

tion of staphylococci than in those in which treatment was begun before injection

It is significant that the cerebrospinal fluid cultures remained positive for several (or many) days even in those treated animals which recovered. This is in support of the now generally accepted concept of penicillin as a bacteriostatic agent

Chart 5—The effect of treatment of staphylococcic meningitis with daily intracisternal injections of 50 units of penicillin

At no time were any harmful effects attributable to penicillin observed

COMMENT

A survey of all our experiments (chart 6) suggests that frequent intravenous medication with penicillin may be of slight benefit in staphylococcic meningitis. Such benefit, if actually present at all, was very limited in this study. This is not surprising in view of the recent observation of Rammelkamp and Keefer⁹ that "penicillin does not pass through the blood-brain barrier in significant quantities following an intravenous injection of the substance."

On the other hand, our experiments indicate clearly that intrathecal administration of penicillin (even in widely spaced doses now known to be too small) may greatly reduce the mortality rate

Chart 6—Composite chart of three groups

Since these experiments were completed, Rammelkamp and Keefer¹⁰ have reported studies on the effects of intrathecal injection of single large doses of penicillin in normal human beings as well as in several subjects with various diseases of the central nervous system. Their observations indicate that penicillin is absorbed

slowly from the cerebrospinal fluid (although more rapidly in the presence of meningitis than in normal subjects). They also demonstrated the same meningeal reaction which was observed in our experiments. The only toxic reactions observed by them were vomiting and headache in one subject (after intrathecal injection of 10,000 Florey units).

From our experiments it seems justifiable to conclude that intrathecal injection of penicillin is a safe form of therapy and to suggest that this method of treatment will probably be of great value in clinical cases of staphylococcic meningitis.

SUMMARY

Intravenous treatment of experimental staphylococcic meningitis was found to have little if any beneficial effect.

Penicillin, when injected intrathecally, even in relatively large doses, produced a pleiocytosis in the cerebrospinal fluid but no other significant toxic effect.

Intrathecal treatment of experimental staphylococcic meningitis with relatively small doses of penicillin greatly reduced the mortality rate (from 93 per cent in control experiments to 54 per cent in treated animals).

It is suggested that intrathecal penicillin therapy will probably be valuable in treatment of clinical staphylococcic meningitis.

THE PROBLEM OF THE ETIOLOGY OF RAT BITE FEVER

REPORT OF TWO CASES DUE TO *SPIRILLUM MINUS*

PAUL B. BEESON, M.D.

ATLANTA, GA

Evidence at present indicates that two different infectious agents may produce the disease known as rat bite fever. *Spirillum minus* and *Streptobacillus moniliformis*. The clinical manifestations of these two infections may be so similar that differentiation is possible only by demonstration of the causative organisms.¹ Recent reviews of the literature on rat bite fever in America show that approximately 150 cases have been reported and that the majority were regarded as *Spirillum minus* infections, although actual demonstration of the parasite by animal inoculation was carried out in only 23 of the cases.² Dawson and Hobby have questioned this evidence because the laboratory animals used in making the diagnosis may be naturally infected with spirilliform organisms and because *Spirillum minus* has not been demonstrated in the blood of persons suffering from rat bite fever.³ Nevertheless it must be accepted that *Spirillum minus* can produce a disease in man typical of rat bite fever, since a number of patients with neurosyphilis have been inoculated with *Spirillum minus* for therapeutic purposes and the typical clinical picture of rat bite fever has resulted.⁴ Brown

Dr. R. S. Leasingham gave technical assistance in identifying *Spirillum minus*.

From the Medical Service of Grady Hospital and the Department of Medicine, Emory University School of Medicine.

and Nunemaker, after studying the available evidence expressed the opinion that infection with either of the two organisms may follow rat bite but thought that *Streptobacillus moniliformis* infection is probably the commoner of the two. The reasons for uncertainty are that only in a few cases has search for both organisms been made and that the laboratory procedures used have not always been reliable. In the present article I report two additional cases of rat bite fever. *Spirillum minus* was isolated in both instances and cultures for *Streptobacillus moniliformis* were negative. Certain technical details of the laboratory procedures are considered.

REPORT OF CASES

CASE 1—History.—L. G. H., a white boy aged 2 years, was bitten by a rat on the thumb and first finger of the right hand while asleep on Dec. 12, 1942. He was brought immediately to the emergency clinic of Grady Hospital where the wound described as 'multiple lacerations' was cleaned and dressed with 1 per cent sulfathiazole ointment. Antitetanus serum was administered. The wound healed promptly and the child remained well until Jan. 18, 1943, thirty-seven days later when his mother noted that his skin was hot, that he was listless and that there were several small red spots on his face and arms. The next day he improved rapidly and the rash disappeared. Four days later he again became listless and feverish and was brought to the hospital. Examination showed a normally developed child who appeared acutely ill. The temperature was 104 F. His skin was hot and dry and several large irregular erythematous areas were present on his face, neck, abdomen and right arm. There were some swelling and induration at the site of the rat bite. The right axillary nodes were palpable. There were no other physical findings. The erythrocyte count was 3,150,000 per cubic millimeter, hemoglobin was 81 Gm. per hundred cubic centimeters and leukocytes numbered 6,500 per cubic millimeter with 72 per cent polymorphonuclears. The urine was normal. Agglutination tests with typhoid, proteus OX19 and brucella were negative. The blood Kahn reaction on admission was doubtful; two days later it was 2 plus and three days later it was 'doubtful'. No further Kahn tests were done. The tuberculin test was negative.

Course.—The patient's temperature variations and the significant laboratory studies are shown graphically in chart 1. It will be observed that he had three febrile episodes, separated by periods of two to three days of normal temperature. During each of the febrile periods a blotchy erythematous rash was noted on his face and extremities. Between the sixteenth and

Chart 1—Course of temperature in case 1 together with significant laboratory and therapeutic procedures.

twenty-third hospital days three intravenous injections of neosarsphenamine were given. Following these he had one brief rise of temperature but thereafter remained afebrile and was apparently quite well when discharged from the hospital on the thirty-third day. He was seen again at a follow-up visit two months later and was still free from symptoms.

Special Laboratory Examination.—Routine blood cultures in tryptose phosphate broth on the first and eighth hospital days gave no growth. On the thirteenth and fourteenth hospital

days blood cultures were made according to the technic recommended by Brown and Nunemaker for *Streptobacillus moniliformis* with 20 per cent fresh rabbit serum in tryptose phosphate broth. Again there was no growth. In an attempt to demonstrate the presence of *Spirillum minus* 4 mice were inoculated with the patient's blood. Each received 0.25 cc. of fresh unclotted blood intraperitoneally. The blood of each mouse was examined by dark field microscope before inocula-

Chart 2—Course of temperature in case 2 together with significant laboratory and therapeutic procedures.

tion and also on the seventh and fourteenth days afterward, but no spirilla were found. On the sixteenth day however, *Spirillum minus* was observed in the blood of 1 of the 4 mice, and on the eighteenth day it was present in the blood of all 4 mice. During the succeeding four weeks *Spirillum minus* was easily demonstrated in the blood of all 4 mice.

CASE 2—M. L. H., a white woman aged 59, married, came to the emergency clinic of Grady Hospital on the night of Nov. 2, 1942, a few hours after she had been bitten by a rat while sleeping. There was a small puncture wound on the right side of her face near the angle of the jaw. This was treated with chromic acid and she was given antitetanus serum. On November 19, seventeen days later, she returned to the clinic because of a soft swelling in the region of the bite. Her temperature was 99.6 F. The swelling seemed fluctuant and was incised but no pus was obtained. She returned for a dressing on November 23, at which time the wound was almost healed. She was not seen again until Feb. 1, 1943, when she returned to the medical clinic complaining of pains in her extremities, weakness, loss of appetite, spells of nausea and vomiting, and some loss of weight. She did not remember dates very accurately, but questioning indicated that she had felt well until about December 25, which was fifty-three days after the rat bite. At that time she had a febrile illness which she thought was "influenza." This had been characterized by chill sensation, never aching in the muscles and a "head cold" and had lasted for approximately two weeks. From that time until admission to the hospital she was never entirely well. There had been episodes every few days of feverishness, chilliness, nausea and vomiting. About January 10 she had noted a painful swelling of her hand, forearm and elbows and one week later there was a similar swelling of her feet and ankles, first on the left side and then on the right. She was admitted to the hospital for study. On physical examination she appeared poorly nourished but not acutely ill. There was no fever. The skin was sorely hot, dry and scaly. A few small non-tender lymph nodes were noted in the right submaxillary and posterior cervical region. The heart and lungs were normal. The blood pressure was 110/70. The abdomen was not tender, the liver edge was just palpable, the spleen was not felt. Over the right hip and leg was a soft pitting edema and the entire area was somewhat tender on pressure. Dorsal flexion of the right foot was painful. These findings were interpreted as evidence of thrombophlebitis in the right leg. Routine laboratory examina-

tions showed erythrocytes 3,600,000 per cubic millimeter, hemoglobin 9.5 Gm per hundred cubic centimeters, leukocyte count 7,800 with 87 per cent polymorphonuclears, sedimentation rate 82 mm per hour, blood Kahn test negative, urine normal.

Course.—The patient's temperature and significant laboratory studies during her hospital stay are shown graphically in chart 2. It will be noted that she had three febrile episodes at approximately five day intervals and that no further episodes occurred after she was given injections of neorsphenamine. The leukocyte count rose sharply when she developed fever. A diagnosis of rat bite fever was not suspected until some days after admission and initial studies were concerned with the function of her stomach and gallbladder. On the twelfth hospital day, when she had fever, the following note was made on her record: "There is a diffuse erythema over the outer surfaces of the arms, a slight splotchiness over the abdomen, and the skin of the right leg below the knee is diffusely reddened and warm. There is a fairly marked erythema surrounding the original area of the rat bite. There is no new lymphadenopathy, though there are small nontender nodes in the submaxillary region." At the onset of the third paroxysm of fever, special laboratory procedures for the identification of *Spirillum minus* and *Streptobacillus moniliformis* were carried out, and following that she was given three intravenous injections of neorsphenamine at two day intervals, as indicated in the chart. This effected a pronounced and rapid clinical improvement, the nausea and vomiting ceased and the pain and swelling in her extremities disappeared. She left the hospital, feeling entirely well, on the thirty-first day. Four weeks later she returned to the outpatient clinic for follow-up and reported herself entirely well.

Special Laboratory Examinations.—Routine blood cultures on the sixth and eleventh hospital days were negative. On the sixteenth and seventeenth days two more cultures were made according to the technic of Brown and Nunemaker, using 20 per cent fresh rabbit serum in tryptose phosphate broth, but *Streptobacillus moniliformis* was not obtained. In an attempt to find *Spirillum minus*, mice were inoculated with the patient's blood on the seventeenth day. Four mice each received 0.5 cc of fresh uncitrated blood intraperitoneally. One of these mice was killed by its cage mate two days later. Examinations of the blood of the remaining 3 mice were made on the third, twelfth and fourteenth days after inoculation, and *Spirillum minus* was not found. On the seventeenth day *Spirillum minus* was found in the blood of 1 of the mice but not in the other 2. On the twenty-first and thirtieth days the same mouse was positive and there appeared to be a considerably larger number of spirilla present. The organisms were never found in the blood of the other 2 mice.

LABORATORY EXAMINATIONS IN RAT BITE FEVER

Streptobacillus moniliformis has been isolated by routine blood culture on a number of occasions, but Brown and Nunemaker advise a modification of the routine procedure when this organism is suspected.¹ Their technic consists essentially in centrifuging citrated blood and then culturing the blood cell residue in test tubes containing fresh serum and a nutrient broth. Under these conditions the "fluff ball" colonies are easily seen and can be withdrawn with a pipet for staining or subculture. Wayson's stain was recommended for studying the morphology of the organisms. This technic was carefully followed in the present cases. Any formation on the surface of the blood cell layer which was suspected of containing bacteria was stained by Wayson's and other methods, but the results were always negative.

Suitable precautions were taken to eliminate the possibility of preinfection in the mice used in the isolation of *Spirillum minus* from these 2 patients. Not only were there several negative preliminary examinations

on the test mice but as a further precaution 14 cage mates which had not been inoculated were also examined. *Spirillum minus* was not present in the blood of any of the animals. Furthermore, the animals used in the 2 cases were different breeds of mice. Those used in case 1 were brown mice which had been obtained from South Carolina, while those used in case 2 were white mice which had been obtained in Atlanta.

Spirillum minus is not difficult to identify when present in the peripheral blood of a mouse. A drop of blood, obtained by snipping off the end of the tail with scissors, is pressed out very thinly with a cover slip on a slide, and the preparation is examined in a dark field microscope. McDermott has written an extensive description of this organism.⁵ The most striking characteristic is its extremely rapid motility. In a fresh preparation it darts in and out of the field very rapidly, however, after an hour or more the motility is often considerably slower. Under these circumstances it is easier to observe the morphology. The organisms are 2 to 5 microns in length, and there are usually two to five spirals. Flagella can be seen as a hazy appearance at the ends. In addition to visibility in the dark field they can also be seen in stained preparations. Ripley and Van Sant have published excellent photomicrographs.⁶

Emphasis is needed on the point that the appearance of the spirillum in the peripheral blood of an inoculated animal may not occur until the third week. Some textbooks and writings on the subject state that it appears between the fifth and fourteenth days. In the 2 cases reported here the spirillum was not found until the sixteenth and seventeenth days, and in other instances the first appearance has been as late as the thirty-seventh day.⁵

COMMENT

These 2 patients with rat bite fever were in the hospital at the same time but were otherwise not related. Some of the clinical features showed striking similarities. The incubation periods were long, the skin eruptions resembled each other closely, the fevers were of the same type, and both infections responded promptly to neorsphenamine therapy. Points of dissimilarity were the prominence of nausea and vomiting in case 2 and the leukocytosis which accompanied the febrile periods in case 2. Neither patient exhibited evidence of arthritis while under observation, although patient 2 gave a history of swelling around the wrists, elbows, knees and ankles before admission to the hospital.

It is of interest that three other cases of rat bite fever due to *Spirillum minus* have been identified in Atlanta,⁷ whereas in Brown and Nunemaker's study of 8 cases in the Baltimore area *Streptobacillus moniliformis* appeared to be the etiologic agent in every instance. Possibly these differences are due to variations in the parasites harbored by rats in different localities.

SUMMARY

In 2 cases of rat bite fever *Spirillum minus* was isolated from the blood by mouse inoculation. Culture of the blood for *Streptobacillus moniliformis* were negative.

AND

CAPTAIN L. ROLAND KUHN

SANITARY CORPS, ARMY OF THE UNITED STATES

From Jan 1 1943 to April 30 1943 more than 1 300 cases of meningococcic meningitis occurred among military personnel in the Fourth Service Command. During this period the attack rate for the disease varied widely from post to post. In some installations only sporadic cases were found; in others the number of cases reached epidemic proportions. Generally speaking, however, the disease was more prevalent in stations where large numbers of recently inducted men were assembled for training purposes.

The customary control measures employed during outbreaks of meningococcic meningitis include quarantine, prevention of overcrowding, protection from fatigue and exposure, and the prompt hospitalization or isolation of all cases of common respiratory illnesses. It is admitted, however, that these measures are only partially effective and, under conditions of active military training, can be properly applied only with considerable difficulty. It seemed desirable, therefore, to seek additional means of controlling this disease particularly among the relatively "unseasoned" recent inductees.

To be useful under military conditions, any control measure proposed must be applicable to large numbers of individuals without causing serious interruptions in daily activities. The remarkable effectiveness of sulfadiazine in the treatment of meningococcic meningitis suggested that it might be of prophylactic value in the control of this disease among troops. There is evidence that other sulfonamides, namely sulfanilamide and sulfapyridine, may have some prophylactic value in curbing outbreaks of meningitis and eliminating meningococci from the nasopharyngeal mucosa.¹ Dingle

and his associates² have pointed out that meningococci disappear promptly from the nasopharynx of patients undergoing treatment with sulfadiazine. This implies that sulfadiazine may be effective in the treatment of meningococcus carriers. Although the exact role of the carrier in relation to the spread of meningococcic meningitis is not entirely clear, it seems logical that a measure which can quickly reduce the carrier rate to a low level may be valuable in retarding sharp outbreaks of this disease. Indeed, reports transmitted from the Office of the Surgeon General have indicated that sulfadiazine has been of value in controlling meningitis at several army posts in recent months.

Studies undertaken at the Fourth Service Command Laboratory have shown that meningococci are rapidly eliminated from the nasopharynx following the peroral administration of 3 Gm of sulfadiazine daily for three days. In a small series of persistent carriers treated in this manner, nasopharyngeal cultures became negative for meningococci twenty-four hours after the initiation of therapy, and repeated nasopharyngeal cultures obtained at weekly intervals remained negative for varying periods of observation up to eight weeks. These results suggested that it might be possible by treating all members of a closed group with sulfadiazine at one time to decrease the number of individuals harboring meningococci during epidemic periods to a point where few, if any, cases of meningitis would occur. Our purpose in this communication is to report the results of the large scale prophylactic administration of sulfadiazine to more than 15,000 soldiers stationed at two posts where meningococcic meningitis was particularly prevalent during the spring of 1943.

CAMP A

Occurrence of Meningococcic Meningitis—Camp A is a newly constructed installation located in rural Mississippi. The camp was first occupied by troops in August 1942, but as late as January 1943 the total military population had reached only 3 100. Thereafter the strength of the post rose rapidly until on March 15 1943 over 34 000 soldiers were stationed there. These included approximately 15,000 men who had arrived at Camp A during the latter part of February 1943 to form the M Infantry Division. The majority of this division was made up of men under 20 years of age who had been inducted into service during the preceding sixty days and who had been assembled from all regions of the United States. The M Division was barracked in areas III, IV, and VI of Camp A (fig 1). These areas are geographically and functionally separate from one another and at the time of this study were reserved solely for this organization. Two infantry regiments were assigned to area III while areas IV and VI were occupied by an infantry regiment, the division artillery, and special troops. Members of the division were housed in 32 man barracks of the theater of operations type. Forty-two men occupied double-decked bunks in each barracks, sleeping in head to foot arrangement. Shortly after arrival at Camp A all men assigned to the M Division began a course of basic training. The program did not seem to be excessively rigorous and physical exhaustion was no greater than might be expected in fresh troops recently inducted from civilian life.

From the Fourth Service Command Medical Laboratory, Fort McPherson, Georgia.

The cooperation of Col. S. W. French, M. C. Col. C. G. Souder, M. C. Col. H. M. Thomas, Jr., M. C. Col. D. C. Campbell, M. C. Col. T. E. Scott, M. C. Lieut. Col. George Prazak, M. C. Lieut. Col. T. served as a control The approximate strength of this group was 9,500 men During the week immediately prior to therapy, the weekly attack rate for meningococcic meningitis in the group to be treated had risen rapidly from 0.0 to 1.0 per thousand This compared with a weekly rate of 0.41 per thousand in the control group at that time

Before the institution of prophylactic therapy the incidence of meningococcus carriers in the treated and control groups was estimated in a manner similar to that previously employed at Camp A The carrier rate in the group to be treated was 30.0 per cent, in the control group the rate was 29.0 per cent Of the meningococci found in these carriers, 37.2 per cent were group I micro-organisms

Results—In a period of observation which extended for eight weeks after the institution of treatment, 2 cases of meningococcic meningitis occurred in the N Division among troops who received the drug⁴ In the untreated group, however, 17 cases were found during this time These results are shown graphically in figure 4 For purposes of comparison the hospital admission rate for meningococcic meningitis in all organizations other than the N Division from March 10 to June 2 is also included in figure 4 These data confirm the findings initially observed at Camp A and in addition indicate that the prophylactic peroral administration of as little as 2 Gm of sulfadiazine daily for two days is effective in curbing outbreaks of cerebrospinal fever among large numbers of troops

Because additional studies undertaken at Camp A had suggested that smaller doses of sulfadiazine might also be effective as a prophylaxis in cerebrospinal fever, all individuals in the treated group in the N Division were given at the same time 1 Gm of sulfadiazine by mouth twice daily for two days The drug was issued to the men as they entered the mess halls for breakfast and supper Treatment started on the evening of April 7 and was completed on the morning of April 9 Precautions similar to those at Camp A were taken to ascertain that each man swallowed the tablets In this instance, however, no instructions regarding possible toxic symptoms were given, since it seemed desirable to observe the treated group without introducing the factor of suggestion

At intervals subsequent to the completion of prophylactic treatment, meningococcus carrier studies were undertaken in the treated and control groups As at Camp A, the nasopharyngeal cultures were obtained each time from the same men originally included in the carrier surveys The results of these observation are set forth in table 2 These findings are essentially the same as those observed at Camp A in that the prophylactic administration of sulfadiazine by mouth appreciably reduced the meningococcus carrier rate among the men who received the drug

4 One of these men had been admitted to the Station Hospital for measles Nine days after admission, while still hospitalized, he developed meningitis The other man was transferred to an organization three weeks after he had received the drug Fourteen days after transfer, signs of meningitis appeared

The administration of 2 Gm of sulfadiazine daily for two days apparently caused very few toxic symptoms among the 7,000 treated men in the N Division. There was no interference with the scheduled basic training program during the period of treatment. Indeed, the questioning of a large number of men by regimental medical officers and the staff of the Fourth Service Command Laboratory failed to reveal the occurrence of any definite toxic effects. It will be remembered that efforts were made to eliminate the factor of suggestion during the treatment of this group. Blood sulfadiazine levels, obtained at random from 20 men two hours after the third dose of sulfadiazine and eight hours after the last dose, ranged from 27 to 54 per hundred cubic centimeters by the method of Bratton and Marshall.³

COMMENT

These data indicate that the prophylactic administration of sulfadiazine by mouth, even in relatively small doses, is a safe and effective method for curbing epidemics of meningococcic meningitis among large numbers of troops. This method of prophylaxis might also prove to be of value in terminating outbreaks of this disease in other situations, for example on troop transports at sea or in schools, orphanages and other institutions.

In these studies the drug was given at one and the same time to all members of the groups to be treated. It should be emphasized that these were closed groups in which there was little opportunity for the usual fortuitous reinfection from outside sources to occur. It seems probable that the effectiveness of the prophylaxis described herein depended on (1) treating all individuals in the group simultaneously, (2) treating all personnel who joined the group subsequent to the institution of prophylaxis before they were incorporated into the group and (3) keeping the treated group closed to reinfection from outside sources.

SUMMARY

1 Sulfadiazine was administered prophylactically to more than 15,000 soldiers in residence at two posts where meningococcic meningitis was particularly prevalent during the spring of 1943. In one instance 3 Gm of drug was given by mouth daily for three days, in the other the dose was 2 Gm daily for two days.

2 Following the institution of prophylactic therapy the incidence of cerebrospinal fever among the treated individuals fell abruptly. Only 2 cases of the disease occurred during a subsequent period of eight weeks of observation. At the same time 40 cases were found among 18,800 untreated controls.

3 Meningococcus carrier surveys showed that the administration of sulfadiazine by mouth effectively lowered the carrier rate in the treated group at a time when the incidence of carriers among the untreated controls remained high or actually increased.

4 No serious toxic reactions resulted from the large scale administration of the drug. The treated men continued their usual daily activities without interruption of the scheduled basic training program during the period of treatment.

Clinical Notes, Suggestions and New Instruments

A CASE OF STAPHYLOCOCCIC ACTINOPHYTOSIS (BOTRYOMYCOSIS) IN MAN

THE TENTH REPORTED HUMAN CASE

CHARLES H. DRAKE, PH.D., MERVIN T. SUDLER, M.D., PH.D.
AND RALPH I. CANUTESON, M.D., LAWRENCE, KAN.

At the present time the rapid advances in chemotherapy make it increasingly important to identify precisely the etiologic agents of infections, since in many cases the selection of a chemotherapeutic drug for treatment is as dependent on the nature of the infecting organism as it is on the clinical picture of the disease. With this in mind we believe it might be of value to report a case of a rare infection in man and point out the ease with which the disease can be misdiagnosed.

T. S. V., a white man aged 21, married, a medical student, consulted a physician in the clinic on June 5, 1943 about a small mass near the anus, present for about two months and uncomfortable only in certain sitting positions. He knew of no injury to the area.

Examination showed a mass about 10 mm in diameter situated in the fatty tissue of the perineum just medial to the tuberosity of the left ischium and a smaller one medial to this but with no demonstrable connection with the anus. The superficial skin was mildly reddened over the larger mass. The mass was easily circumscribed and only slightly tender. Rectal examination gave no additional information.

The impression was that this was an infected sebaceous cyst and the patient was advised to use hot compresses over the area affected.

On June 12 he was seen again. There was no localization of the infection. He was hospitalized for hot compresses, because he was uncomfortable sitting in class and had poor facilities for treatment at his home. His temperature was normal. The white blood count was 9,600 with 67 per cent polymorphonuclear cells, 30 per cent lymphocytes, 1 per cent monocytes and 2 per cent eosinophils.

On June 14 the mass was incised, yielding about 2 drachms of granular sanguinopurulent drainage. Recovery was rapid. He was dismissed from the hospital on June 16 with the incision closed. There has been no recurrence to date.

Pus removed from the abscess at operation was examined at the department of bacteriology and found to contain small white granules about half again as large as a pinhead. Under the microscope these granules were coarsely lobulated and the surface was covered with tightly packed clublike projections. Under both the low and high powers of the microscope the granules appeared identical with the sulfur granules observed in actinomycosis when they were examined either as fresh mounts or after treatment with 20 per cent potassium hydroxide solution. Gram stains were prepared from a crushed granule but instead of showing the characteristic fragments and fine branched gram-positive mycelium as are found in true sulfur granules, only masses of staphylococci were present. Smears from a number of the granules yielded the same results, but a careful examination of smears prepared from the pus surrounding the granules showed only a few staphylococci after long examination. The cells present were considerably disintegrated and consisted chiefly of polymorphonuclear neutrophilic leukocytes and considerable numbers of mononuclear cells. The presence of granules composed of masses of staphylococci with few of the bacteria round outside the granules identifies the infection as staphylococcic actinophytosis or botryomycosis. Cultures from the crushed granules yielded a pure culture of *Staphylococcus aureus*. This was somewhat less pigmented than usual and showed no hemolysis on blood agar but was coagulase positive and gave the usual cultural reactions.

From the Department of Pathology, University of Kansas School of Medicine (Dr. Drake) and the Walter Memorial Hospital, University of Kansas (Dr. Sudler), and the Lawrence and Dr. Canuteson's Private Sanitation Health Service.

Botryomycosis was described by Bollinger¹ in 1870 as a disease of horses, usually following castration by crude methods, characterized by a granulomatous lesion that slowly involves the surrounding tissues but only rarely becomes generalized. In pus discharged from the lesion the causative organism occurs as small, lobulated and frequently clubbed granules which were believed to be mycotic in nature and were assigned to the genus *Botryomyces*. The infection has also been reported in other animals.²

The true nature of the disease was shown by Magrou³ in 1914. This author carried out a complete investigation which showed that the causative organism was *Staphylococcus aureus*, identical in all respects with ordinary strains of the bacterium but which occurred in the tissues in the form of peculiar granules rather than scattered throughout the pus as in ordinary staphylococcal infections. Magrou showed that these granules were composed of masses of staphylococci embedded in a matrix and were usually surrounded by some kind of membrane. The periphery of the granules, which were usually lobulated, was frequently covered by closely packed clubs as in the sulfur granules of actinomycosis. He pointed out that the lesions in horses usually contained horsehairs as foreign bodies and was able to reproduce the disease in rabbits and guinea pigs by inserting into the testes horsehair contaminated with staphylococci. Further work showed that foreign bodies were not absolutely necessary but that the disease could be produced in experimental animals by the injection of small numbers of *Staphylococcus aureus*. It was necessary to have the number of organisms within a definite range so that there were too few to produce a purulent inflammation but yet sufficient so that they would not be absorbed with little or no tissue reaction. Once the correct range has been established for any culture, the disease could be produced at will both with cultures isolated from botryomycosis and with ordinary strains of staphylococci.

In his paper, Magrou recorded from the literature (Kaiser and Gryns) one probable human case of botryomycosis occurring as an osteomyelitis. Since that time 8 other human cases have been recorded. Masson⁴ in 1918 reported a second case in man, also occurring as an osteomyelitis, following a hip fracture by a shell fragment. Two cases of nontraumatic osteomyelitis of botryomycotic nature were reported by Fumagalli⁵ in 1928. Berger and his associates⁶ reported the fifth case in 1936 and the first case in which the infection was confined to soft tissues, occurring as an infection of the genital tissues of a woman. They also point out that a much more common infection in man, granuloma telangiectaticum, has erroneously been called botryomycosis and, since in addition the true disease is not a mycosis, suggest that the infection might better be termed "staphylococcic actinophytosis." The sixth human case was observed by Plaut⁷ in 1937 as an abscess of the abdominal wall, which contained a broom straw in addition to the typical granules. The seventh and eighth cases were observed by Kimmelstiel and Oden⁸ in 1939 as abdominal abscesses, both of which contained fragments of fish bones. One of these cases was admitted by the authors to be questionable. The ninth case was recorded in 1941 by Fink⁹ as a liver abscess with involvement of the lung by both direct extension and metastases.

It would appear from the small number of reported cases that the disease is rare in man, but there can be little doubt that this rarity is more apparent than real. Of the recorded cases several have been diagnosed only by the examination of tissues removed at autopsy or at operation, so that many cases are no doubt missed. This infection can readily be confused with actinomycosis or may be dismissed as a simple, chronic,

inflammatory process. The granules are usually quite small and readily overlooked unless the pus is carefully examined with the naked eye. Simple smears of the exudate are unlikely to contain the granules, so that there can be little doubt that in many cases the granules have been overlooked. Plaut especially points out the importance of differentiating between botryomycosis and actinomycosis, since the prognosis is more favorable in botryomycosis and less radical treatment is necessary. This is borne out by our case, which responded readily to simple drainage. Of the reported infection involving only soft tissues, Berger's patient was still alive twenty months after the onset although unimproved, Plaut's patient recovered rapidly after operation, one of Kimmelstiel and Oden's patients died of complications following operation but the other was completely cured one month after operation, and Fink's patient died from a generalization of the infection but the disease was not diagnosed until autopsy.

Confusion in diagnosis would arise from observation of the granules in fresh material since they are almost identical under low and high powers of the microscope with the granules observed in actinomycosis. It is essential that crushed granules be examined by means of the gram stain. This procedure readily shows that the granules are composed of staphylococci rather than the branched, fine, gram-positive mycelium that makes up the sulfur granules of true actinomycosis. This procedure should never be neglected, since this is necessary to differentiate between the granules of staphylococcic actinophytosis, actinobacillosis, actinomycosis and mycetoma. In staphylococcic actinophytosis the granules are composed of masses of staphylococci embedded in a matrix of some kind and are usually surrounded by a refringent membrane the surface of which is often bedecked with clubs. Occasionally granules from old lesions are calcified. The nature of the matrix and of the limiting membrane are the subject of some dispute. Some authors believe that either or both materials arise from the organisms, probably from proteins derived from disintegrated bacteria. However, others believe that either or both of these substances arise from the host tissues. In some cases it would appear that the hard membrane described was due to calcification. Kimmelstiel and Easley¹⁰ claim to have produced the disease in experimental animals and to have traced the development of the matrix from disintegrating tissue elements. This problem, however, is common to the formation of club covered granules in all of the diseases mentioned and need not be considered here in any detail.

Even considering the fact that many cases of this disease are probably overlooked, it still seems to be less common in man than in lower animals and especially the horse. This is rather surprising in view of the fact that staphylococcal infections are more common in man than in the lower animals. Although Magrou considered that the natural development of the disease was primarily due to infection with a limited number of organisms, this view has been questioned by several authors, who point out that man is frequently, if not more frequently, exposed to infection with a limited number of staphylococci. The importance of foreign bodies has been stressed by a number of workers, and their importance in the development of experimental infections has been shown by Kimmelstiel and Easley. In at least 7 of the reported cases in man, foreign bodies, such as bony sequestrums, fish bones and a broom straw, have been found in the lesions.

We would suggest, at present on purely theoretical ground, that the development of the disease is dependent on a careful balance between the defense mechanisms of the host and the invasive powers of the organisms. Several workers have pointed out the rather low virulence for experimental animals shown by cultures of *Staphylococcus aureus* isolated from staphylococcic actinophytosis. In our case the organisms presented the anomalous characteristic of lack of hemolytic power but was still coagulase positive, as is characteristic of most pathogenic strains. This lower virulence is a point in favor of our theory, as is the fact that the infection is more common in animals possessing a higher natural resistance to staphylococci than that shown by man. The disease probably develops as a result of the entrance into the tissues of staphylococci of low invasive powers but which are able to maintain themselves.

there often aided by the presence of foreign bodies. This would cause the formation of a chronic inflammatory process with a purulogranulomatous tissue reaction. It is a fundamental peculiarity that all of the infections characterized by the growth of the organisms in granules are also characterized by at least a partially granulomatous tissue reaction.

TREATMENT OF VINCENT'S ANGINA OF THE TONSIL

A PRELIMINARY REPORT

MAJOR C. S. LINTON

MEDICAL CORPS ARMY OF THE UNITED STATES

The great number of methods and combinations of drugs used by various clinicians in treatment of Vincent's angina indicates that none of them have proved entirely satisfactory. It is a common experience, whether infection is present in the gums or in the pharynx, to have these patients returning frequently over a long period of time. An apparent cure within a period of ten days is usually considered quite satisfactory and even then, owing to frequent recurrence, the wise clinician avoids assuring his patient that he is completely cured.

The fusiform organisms and spirochetes of Vincent's angina have many of the characteristics of a secondary invader. It is commonly believed that these organisms enter only into tissues weakened by some other cause. What this cause is has not definitely been determined but there is some evidence that nutritive factors play a part. It is also possible that some associated infection may prepare the ground.

Vincent's infection of the tonsil was seen recently in several soldiers returning from the South Seas. These men had been exposed to strenuous physical conditions for a considerable period of time with meager rations while on front line duty. They were all sent back to the zone of the interior with various types of disability. On account of the likelihood of a pronounced increase of cases of this type under war conditions, it is considered advisable to make this preliminary report showing remarkable recovery under treatment with sulfathiazole. The first 2 patients had initial treatment with other methods without effective results. Each patient reported definite improvement in soreness of the throat within twenty-four hours with most symptoms gone in forty-eight hours and practically complete clinical recovery within seventy-two hours under treatment with sulfathiazole.

The dosage and method of administration ultimately used consisted of a 0.5 Gm. sulfathiazole tablet dissolved on the tongue every two hours during the day and 1 Gm dissolved on the tongue every four hours during the night. This was continued for two days at which time the patient would voluntarily discontinue medication unless directed otherwise because symptoms had disappeared. When infection also was present about the gum margins it was advised that the sulfathiazole tablet be moistened with a few drops of water to make a paste and this used to rub into the gum margins. Excellent results were secured on the gums in 1 case using this method but it was not tried sufficiently to warrant any expression of opinion.

A search of the literature fails to reveal any use of sulfonamide drugs for this purpose except 1 case treated by Pelner.¹ A remarkable cure was secured with azosulfamide. However Spink in his book on 'Sulfanilamide and Related Compounds' states that sulfanilamide has been used in treatment of gingival infections such as pyorrhea and Vincent's angina with no benefit from local or oral administration.

REPORT OF CASES

CASE 1—E. E. B. A man aged 26 was sent in with a sore throat of seven days duration and a grayish membrane on the tonsil. Microscopic examination showed great masses of fusiform bacilli and spiral forms from the necrotic area. He was given 0.045 Gm of mapharsen intravenously and local treatment to the tonsil consisting of aqueous 10 per cent mercur

rochrome. I had previously secured excellent results by using nearsphenamine intravenously but at this time the drug was not available. The patient returned in two days with the throat still very sore, and local treatment with silver nitrate and mercurochrome was given. The same treatment was repeated the following two days and owing to some ulceration of the gum margin anteriorly, it was advised that sodium perborate paste be massaged into the gums three times daily. On the fifth day little improvement was noted in the condition so it was decided to give sulfathiazole orally, 1 Gm every four hours, in addition to local treatment. The throat was much improved the following day and after forty-eight hours recovery was sufficiently complete to warrant stopping treatment. Some ulceration of the gum margins remained. It was advised to continue sodium perborate paste for two or three days. Tonsillectomy was done under local anesthesia in about another week.

CASE 2—S. W. S., a boy aged 13 years, received with a diagnosis of membranous pharyngitis of three days' duration gave no previous history of sore throat but had suffered from dry cough for about one week. A smear from the tonsils showed large numbers of fusiform organisms and spirals of Vincent's angina. He was first seen on March 26, 1943 and given intravenously 0.045 Gm of mapharsen and sodium perborate paste to the gum margins. After four days there was still some soreness and some membrane present. After several days more of local treatment there was gradual recovery. On April 13 there was an acute recurrence of the infection in both tonsils. Another intravenous injection of mapharsen was given, as well as local treatment to the affected areas. On April 18 infection was still present and sulfathiazole 1 Gm every four hours to be dissolved on the tongue, was ordered for two days. Two days later the patient was seen and had no complaints. Ulcerations had disappeared and there was no soreness in the tonsils although there was still some infection in the gum margins. Tonsillectomy was done two days later with good results.

CASE 3—C. J. L., a man aged 23 who complained of sore throat for about ten days had a deep ulceration in the middle of the left tonsil. A smear from this area showed many fusiform organisms and spirals of Vincent's angina. The treatment consisted only of sulfathiazole 0.5 Gm on the tongue every two hours during the day and 1 Gm every four hours during the night for two days. The patient failed to return as directed. He was looked up after six days and it was found that he had felt well after two days and saw no need for returning. He was much improved after twenty-four hours. In order to prevent recurrence he was advised to take a high vitamin diet including considerable orange or grapefruit juice, greens and brewers' yeast.

CASE 4—B. N., a youth aged 20 complained of sore throat of two days duration. An ulcerated area was present in the right tonsil and there was much ulceration of the gum margins. A smear from the tonsil showed numerous fusiform organisms and spirals of Vincent's angina. The gum margins could bleed profusely from the slightest touch. He was first seen on May 18, 1943 and given sulfathiazole 0.5 Gm dissolved on the tongue every two hours during the day and 1 Gm every four hours during the night. The next day he was much improved with the soreness of the throat much better and the ulceration in the tonsils and gum margins apparently much improved. On the third day no soreness remained and the throat and gum margins appeared practically healed.

On account of the probability of an increase in epidemics of this type due to war conditions and a lowering of the general nutritive condition in certain groups or areas it is hoped that others will try this method of treatment where more cases are available for observation. In the case reported dietary advice or brewers' yeast were not given until the acute condition had been controlled.

The 4 cases reported are the first 4 cases treated with sulfathiazole. The very remarkable results suggest that it may be a specific cure for the condition although it is impossible to draw any conclusions. It is believed that recurrence of the infection are likely to occur from any type of treatment unless factors which cause weakened resistance in the tissues are controlled.

HANDBOOK OF NUTRITION. XXIV

NUTRITION IN PREVENTIVE MEDICINE

W. H. SEBRELL, MD

Senior Surgeon, U. S. Public Health Service, Chief, Division of
Chemotherapy, National Institute of Health

BETHESDA, MD

(Continued from page 337)

VITAMIN B₁ (THIAMINE) DEFICIENCY

Vitamin B₁ (thiamine) deficiency has been known since antiquity by many synonyms: polynemitis endemica barbars (France) loempoe (Java) kakke (Japan and China) taon (Philippines), maladie des sucres (French Antilles) hinchazon (Cuba) mucasas or perneiras (Brazil) maladie des jambes (Louisiana)¹⁰⁹

The classic type of beriberi is characterized by symptoms due to damage of the nervous and cardiovascular systems and produces neuritis and heart failure. In the so-called "dry" type of the disease the nervous manifestations are the predominant symptoms and in the "wet" type the edema of heart failure is the more striking sign. Various combinations may exist. The neuritic form is seen most commonly in the United States¹¹⁰ except in some areas of Louisiana where classic beriberi occurs.¹¹¹ Infantile beriberi occurs in breast fed infants of mothers with the disease.

Geographically the disease is widespread, occurring endemically or sporadically in all parts of the world. The classic form is common in Asia and Australasia. It occurs with less frequency in Africa, South and Central America, Europe and the United States (table 5). In the latter country about 20 per cent of chronic alcoholic addicts have neuritic manifestations of the disease.¹¹⁰ Infantile beriberi has a death rate of over 90 per cent and is a chief cause of infant death in the Far East.¹¹²

NICOTINIC ACID DEFICIENCY (PELLAGRA)

Deficiency in niacin (nicotinic acid) or closely related substances results in the disease pellagra. The most prominent symptoms of pellagra are stomatitis, dermatitis, mental changes, gastrointestinal upsets and weakness. Pellagra occurs most commonly in people of poor economic status because of the greater food restrictions in this group. In the United States most of the cases occur in the Southeastern states in the spring and early summer.

From 1933 to 1940 the annual death rates from pellagra in thirteen states of the Southeastern United States varied between 5.1 to 22.4 per hundred thousand of population.¹¹³ In 1941, four years after the discovery that nicotinic acid was the pellagra preventive vitamin, 1,868 deaths were reported from pellagra in the United States.¹¹⁴ Many other reports offer strong evidence that pellagra remains prevalent in the United States.

114 Division of Sanitary Reports and Statistics, U. S. Public Health Service personal communication to the author.

Bean, Spies and Blankenhorn¹¹⁵ estimate that 1 to 2 per cent of all admissions to the medical services of the Lakeside Hospital, Cleveland, and the Cincinnati General Hospital were due to pellagra. Goldsmith¹¹⁶ found evidence of pellagra in 17 per cent of 200 consecutive admissions to the medical services of the Charity Hospital, New Orleans. Many other reports of cases of pellagra both within and without the endemic areas in the United States are summarized in table 6.

Outside the United States the great endemic areas appear to be Egypt, Rumania, Bulgaria and many parts of Africa. Ellinger, Hassan and Taha¹¹⁷ found that 34.3 per cent of 204 people examined in lower Egypt had signs of pellagra. Clark¹¹⁸ states that 201 cases were admitted to the dermatologic service of the Alexandria Hospital in 1931-1933 and that the incidence at the Cairo General Hospital was 3 to 24 cases per thousand admissions to the medical services. In 1918 70,000 cases were said to exist in Rumania¹¹⁹ and in 1934 the death rate in Rumania is given as 118 per hundred thousand of population.¹²⁰ The data on Bulgaria are not so definite, but Moloy¹²¹ believes that pellagra is the most common avitaminosis in that country. Trowell¹²² states that pellagra is endemic among the children in certain tribes on the east and west coasts and in Central Africa. Nauck¹²³ makes the astonishing estimate that in Transcaucasia in 1933 there were 30,000 to 50,000 pellagrins in a population of 1,300,000 or a case incidence of 23 to 38 per cent. Alessandri and his collaborators¹²⁴ estimated the number of cases in Chile in 1942 to be 3,000. Smaller numbers of cases have been reported from India,¹²⁵ Russia,¹²⁶ China,¹²⁷ Japan,¹²⁸ South America¹²⁹ and many of the British colonies.¹²⁹ Exclusive of Spain, Italy and the Balkans the disease seems to be only sporadic in Europe.

ARIBOFLAVINOSIS

Ariboflavinosis is a disease due to deficiency of the water soluble vitamin riboflavin. It is characterized by the development of cracks in the skin at the corners of the mouth (cheilosis), a greasy eruption of the skin changes in the tongue and keratitis, caused by an invasion of the cornea by blood vessels.

Because of the recent description of the disease information on its incidence is relatively scanty. In

Hospital, New Orleans. Wiehl and Kruse⁶ found that 75.8 per cent of pupils in a school in the East Side of New York City had signs of mild riboflavin deficiency as did 34.4 per cent of a group of 143 WPA employees. Kruse's figures must be interpreted with care since the diagnoses were made entirely on the changes found in the eyes which by themselves are not specific of riboflavin deficiency. Nevertheless the reports cited plus

probably widespread in India¹²¹ China¹²² Malaya¹²³ and Africa¹²⁴.

VITAMIN C DEFICIENCY

Scurvy is a metabolic disease resulting from a deficiency of vitamin C and characterized by a general

TABLE 6—Incidence of Pellagra

Area and Date	Incidence	References and Comment
1 Southeastern states, U. S., 1912-1919	Death rates per 100,000 population varied between 6.1 and 22.1	De Kleene ¹¹⁷
United States, 1913, 1941	Total deaths from pellagra in United States varied from 1,905 to 1,876	Sanitary Reports ¹¹⁴
Ohio Hospitals, U. S., 1941	Pellagra accounted for 1 to 2% of admissions to medical wards	Bean, Spies and Blankenhorn, ¹¹⁸ noteworthy because outside endemic area
Charity Hospital, New Orleans, 1941	Pellagra found in 17% of 200 consecutive admissions to medical wards	Goldsmith ¹¹⁶
Charity Hospitals, New Orleans and Shreveport, La., 1917-1941	1 to 21 deaths yearly in these 2 hospitals	Jones, R. C. New Orleans M. & S. J. 95:407, 1943, 58 to 162 cases admitted yearly
Michigan, 1940	Signs and symptoms of pellagra frequent in Northern states especially in the alcoholic	Hild, H., Jr. New England J. Med. 223:307, 1940 states that disease is commonly overlooked in the north
California, 1908-1910	Death rates varied from 0.72 to 1.6 per 100,000 population	Smith, C. I., and Stevens, I. M. Am. J. Hyg. 27:590, 1938
Indiana, 1914	Reports 11 cases	Jones, P. J., and Zervas, L. G. J. Indiana State M. 4:27, 196, 1919, all cases admitted to Indianapolis General Hospital
Kentucky, 1914	Reports 11 cases	Koester, J. H., and Blankenhorn, M. J. A. M. A. 112:2881, 1939, all cases occurred in county (Perry)
Alabama 1917	10 cases admitted to Hillman and T. C. 1 Hospitals, Birmingham	Spies, T. D., Chinn, A. B., and McLester, J. B. J. A. M. A. 108:683, 1936
Alabama, 1919	Reports 67 cases of multiple B vitamin deficiency (see riboflavin table)	Spies, T. D., Vetter, R. W., and Ashe, W. F. J. A. M. A. 113:961, 1939 states that multiple deficiency states are very common
Canada, 1917	Reports 1 case	Quentin, J. J. Canad. M. A. J. 47:464, 1942
Ireland and Wales, 1928-1938	77 deaths reported in 10 year period	Registrar General's Statistical Review of England and Wales for the year 1938, New Annual Series, No. 16 H. M. Stationery Office London
Northern Ireland, 1941	16 cases	Deeny, J. Brit. M. J. 1:157, 1942 16 patients with suggestive skin or gastric symptoms were relieved with niacin
Ireland, 1914-1923	5 cases	Davies, J. H. T., and McGregor, H. G. Brit. J. Dermat. & Syph. 51:21, 1950
Ireland, 1941	1 case	Davis, G., and Hinden, J. Lancet 1:10, 1941 patient was alcoholic
Scotland, 1940	1 case	Robertson, D. S. Edinburgh M. J. 47:81, 1940
Italy, 1935	74 deaths in 1937	Statistica delle Cause di Morte nell'Anno 1937
Transcaucasia, 1914	0,000 to 10,000 cases estimated	Nauk, 1-3 total population 1,300,000
Bulgaria	Author saw personally 223 cases in 10 years of practice	Molot, 1-2 the most important avitaminosis in Bulgaria is pellagra
Rumania, 1918	70,000 cases estimated	Stannus, ¹¹⁹ source of figure is not clear in reference
Belgium 1919	1 case	Van Bogaert, L., and Vanden Berghe Bull. Acad. roy. di med. Belgique 4:409, 1939
Switzerland 1918	2 cases	Bickel, G. Schweiz. med. Wchnschr. 68:1159, 1938
Norway, 1911-1919	18 cases	Kickland, J. Nordisk Med. 1:663, 1939
Netherlands 1918	10 cases	De Langen, C. D., Bowslyk, J. C., and van Meunehuizen, C. L. C. Nederl. tijdschr. v. geneesk. 72:4970, 1938
Sweden, 1914	1 case	Mundus, I. Nordisk Med. 1:2477, 1939 many ill defined cases seen
Germany, 1919	1 case	Salm, H. Munchen med. Wchnschr. 86:882, 1939
Spain, 1917-1938	Many in Madrid during and after Spanish Civil War	Jimenez Garcia, F., and Grande Covian, F. Rev. clin. española, 1:313, 1940
Rumania, 1914	Death rate 11.8 per 100,000	Jonesco Mihalesti, Cuica and Cuica ¹²⁰
Rumania (Moldavia) 1918	2 cases in 4 families comprising 3, per sons	Enescu, M., and Rodenschi, A. Abstr. Zentralbl. f. d. ges. Hyg. 41:90, 1938
Brazil, 1930-1937	114 cases at Recife, 16 cases in rest of Brazil	Da Costa and Castro ¹²¹
Argentina, 1941	5 cases reported to 1941	Bickeltruch ¹²² pellagra is rare in Argentina
Chile, 1942	110 cases reported in Santiago	Alessandri ¹⁻⁴ states that there are now 3,000 cases in Chile
Africa, 1937	Describes 26 cases occurring in 1934-1935 in Nairobi Hospital Kenya Colony in children	Trowell ¹⁻² states that the disease is endemic on east and west coasts and in Central Africa
Africa, 1912-1919	145 total	Stannus, ¹¹⁹ figures collected from annual medical reports of colonies
Africa, 1937-1938	171 cases at Abu and Ingos, Nigeria, in 744 persons examined	Moore, D. F. J. Trop. Med. & Hyg. 42:109, 1939
Egypt, 1937	Found pellagra in 34.3% of 204 people examined in lower Egypt	Ellinger, Hassan and Taha ¹¹ pellagra is rare in upper Egypt but does occur
Egypt, 1931-1933	Rate at Cairo General Hospital was 3 to 24 cases per 1,000 admissions depending on the season	Clark ¹¹⁸
Egypt, 1938	15 cases	Alport, A. C., Chalioungui, P., and Hanna, G. Lancet 2:1460, 1938
India	Pellagra is very frequent in a large percentage of infants	Ashroby ¹⁻⁵
India, 1942	Widespread	Batra, ¹⁻⁵ all types of deficiency disease are seen but pellagra is most widespread
India, 1941	Describes 10 cases	Carruthers ¹²⁶
India, 1940	Describes 25 cases incidence 0.6% of admissions to medical wards	Raman, ¹⁻¹⁰ Vizagapatam is an endemic focus of pellagra
India, 1942	Saw 6 cases in 18 months	Ahmed Indian M. Gaz. ¹²⁵
India, 1939	Describes 5 cases, 12 cases seen at the medical school yearly	Sen Gupta, Rai Chaudhuri, Chaudhuri and Napier ¹²⁵
Straits Settlements and Malaya, 1937	20 cases	Ahmed J. Indian M. A. 125 present in upper provinces
Malaya, 1935	'Frequent'	Goodall, ¹⁻¹⁰ in India cases of pellagra are frequently met
Straits Settlements, 1932	64 cases in 10 years with 1 death	Napier ¹⁻¹⁰ thinks pellagra is frequent in India but is not diagnosed
Hong Kong, 1932	3 cases	Ann. Rep. M. Dept. Straits Settlements, Fed. Malay States and F.M.S. Malay States, 1938
Trinidad, 1933	2 cases	Landor, J. V., and Pallister, R. A. Tr. Roy. Soc. Trop. Med. & Hyg. 29:121, 1935, disease sporadic in Malaya
St. Christophers, 1932	1 case	Stannus, ¹¹⁹ quoting reports of medical departments of British colonies
Antigua, 1933	1 case	Wyjasnowsky ¹²⁶
British Honduras, 1932	404 cases	Yang and Huang, ¹⁻¹⁰ occurred in army camp
Bahamas, 1928-1932	20 cases at Tashkent	Yu ¹⁻¹⁰
Russian Turkestan, 1934	30 cases	Wilson ¹²⁷
China, 1934	3 cases	Itoh ¹²⁸
Manchuria, 1934	Present in leprosy colonies	Morris, Hwang and Kuo ¹⁻¹⁰ all from 1 war refugee camp
Korea, 1926	73 cases reported in Japan to 1925	Crabe ¹²⁷
Japan, 1925	40 cases	
China, 1941	30 cases	
Korea, 1939		

debility, progressive anemia and hemorrhagic tendency and skeletal changes of infants and children as the result of arrestment of bone development and hemorrhage.

The disease is of worldwide occurrence. Case studies and group surveys have been reported from Africa¹³³ China¹³⁴ Australia¹⁴⁰ and its territories¹⁴¹ Malaya¹⁴² the Philippines¹⁴³ Czechoslovakia¹⁴⁴ France¹⁴⁵ Norway,¹⁴⁶ Rumania¹⁴⁷ Spain¹⁴⁸ Switzerland¹⁴⁹ the Faroe Islands,¹⁵⁰ Greenland¹⁵¹ the United States¹⁵² and

of 10,000 natives studied had clinical evidence of scurvy. The crowded housing increased incidence of infectious diseases, chronic fatigue and native customs of preparation of food were attributed as causative factors. In several studies where the incidence reported has been based on the demonstration of low blood vitamin C levels in selected groups, the prevalence of hypo-vitamin C appears alarming. During the winter of 1937-1938 among school children studied in Lau-

TABLE 7—Incidence of Riboflavin Deficiency

Area and Year	Incidence	References and Comment
Georgia 1939	3 cases	The Odens and Sebrell ¹³⁰ all had cheilosis
New York 1939	15 cases	Jolliffe W, Fern H D and Rosenblum L A New England J Med 221 24 1939 all had cheilosis
Georgia 1939	6 cases	Sydenstricker V P, Geeslin L E, Templeton C M and Weaver J W J A M A 113 1697 1939 all had cheilosis

England 1942	Not significant	Selected groups of school children and medical students as studied by blood assay	Francis and Wormald ¹⁴⁸ Harris ¹⁴⁹

South America¹⁵³ The endemic or epidemic proportions of the disease depend on many factors. In 1932 a report from Rhodesia¹⁵⁴ revealed that 80 per cent

of 10,000 natives studied had clinical evidence of scurvy. The crowded housing increased incidence of infectious diseases, chronic fatigue and native customs of preparation of food were attributed as causative factors. In several studies where the incidence reported has been based on the demonstration of low blood vitamin C levels in selected groups, the prevalence of hypo-vitamin C appears alarming. Vitamin K deficiency manifests itself as a tendency to hemorrhage, brought about by a lowered prothrombin level of the blood. It is believed that the normal human adult can dispense with this vitamin in the diet because of synthesis by bacteria in the intestine. It follows and is supported by clinical findings that K avitaminoses will be found only in the newborn before

* Normal

† Anemic

‡ Subnormal

§ Standard red blood cells 4100000

In summary it would appear that vitamin C deficiency is of worldwide occurrence in significant numbers of people. Although low blood levels of vitamin C may and do occur without evident manifestations of scurvy, this finding indicates at least an intake of vitamin C below that necessary to maintain the individual's body reserves at the highest level.

the bacterial flora has become established and in adults when there is interference with fat absorption

A tendency to hemorrhage is not a proof of vitamin K deficiency, but it has become well established that this vitamin is of value in preventing hemorrhagic disease of the newborn and the bleeding of obstructive jaundice and a number of other conditions.

Most cases of hypoprothrombinemia except those which are due to liver damage have been found to respond to vitamin K.

160 Croft J D and Snorf L D Am J M Sc 198 40 (Sept)
1939
161 Francis C E C and Wormald A Lancet 1 64 (May 0)
1947 Harris J I ibid 1 642 (May 0) 1942

Avitaminosis K appears to have been studied most extensively in the United States, in Denmark and in the British Isles. Very little information is available from other sections of the world. By far the highest incidence is in the newborn, other cases are negligible in comparison. Estimates of prothrombin deficiency in very young infants range as high as 60 per cent,^{161a} and an incidence of retinal hemorrhage as high as 25 per cent has been observed.^{161b}

NUTRITIONAL ANEMIA

The term "nutritional anemia" is restricted to the anemia resulting from insufficient dietary intake of iron. Anemias indirectly arising from other nutritional deficiency such as that which accompanies scurvy, pellagra or hypoproteinemia are not included here.

Nutritional anemia cannot be regarded as a clearly defined clinical entity. Standards of optimal hemoglobin concentration and optimal red blood cell count for persons of each age, sex or race are not generally agreed on.⁶ Moreover, certain normal physiologic functions such as pregnancy, pubescence, catamenia and the menopause materially alter the blood picture in so complex a manner that the definition of the norm for these special states is uncertain.¹⁶ The situation is further complicated by the fact that other causes of anemia such as chronic latent blood loss, local infection or tuberculosis may be readily overlooked in large scale investigations.

The clinical features of nutritional anemia are likewise not very clearcut. The dietary history affords the most pertinent positive information. In evaluating the dietary history, local variations in the iron content of foods must be kept in mind. The symptoms are somewhat generalized and include lack of energy, headache, vertigo, dyspnea and palpitations. In children, behavior difficulties such as failure to concentrate and physical indolence are observed. The condition is commonly accompanied by no distinct symptoms whatever.

Physical findings include pallor, loss of skin turgor, suboptimal weight and reduced muscle tone. In advanced cases a soft apical systolic murmur may be heard and the pulse is rapid and of poor quality.¹⁶³

Most often, however, the diagnosis rests solely on laboratory findings. Reznikoff states that, "hematologically, the striking features of iron deficiency from any cause are the relatively marked decrease of hemoglobin compared to the red blood cell reduction and the small size of the cells, giving a low volume index, usually less than 0.75."¹⁶⁴

Recent studies have been concerned both with the development of adequate diagnostic standards and with the determination of the prevalence and distribution of the deficiency. Despite numerous fairly elaborate studies, only a beginning has been made. In table 10 there have been summarized those studies of the past decade which afford epidemiologic data concerning nutritional anemia. The groups studied vary widely and include preschool children, school children, pregnant women and general populations. Standards for

the determination of deficiency are frequently not stated and the stated standards vary widely from survey to survey. Moreover, the inherent error in the several laboratory procedures employed in the respective surveys is not at all comparable although in all instances it is admittedly great. For these reasons each of the recorded studies must be regarded as a distinct source of information bearing on the special group, and no general statistical summary is warranted.

Disregarding these limitations, we may observe from isolated studies that at least in certain communities nutritional anemia should be given close consideration. Thus about 50 per cent of 2,400 children studied in Pennsylvania in 1939 were anemic. In Michigan 26.6 per cent of 158 pregnant women were found anemic and in Boston 16 per cent of adults studied were anemic. In New York City 72 per cent of 325 pregnant women were anemic. In Florida in 1939 more than 50 per cent of 620 school children were found to have subnormal hemoglobin. In Scotland, in 1939, 32 per cent of children and 45 per cent of adults examined were anemic, and in Madrid, Spain, in 1941, 16 to 18 per cent of 561 persons had low hemoglobin (table 10).

Accordingly, Jolliffe, McLester and Sherman¹⁶² state that combining such data indicates "anemia in from 15 to 85 per cent of children, 36 to 30 per cent of adults and 9 to 72 per cent in pregnancy." Obviously the wide range of these estimates indicates that they are not particularly informative of the actual occurrence of nutritional anemia in the world population.

Such diverse and yet limited information affords too spotty a view of the character and scope of the problem of nutritional anemia to constitute a basis for sound public health practice. Nevertheless it is clear that where the condition has been searched for many cases have been found. In all probability nutritional anemia is of widespread, worldwide occurrence and further extensive observations should be carried out in order to set up suitable public health and dietary practices to prevent this condition.

THE PROBLEM OF ADEQUATE NUTRITION

International attention was first given to nutrition and health by the League of Nations beginning in 1925 and culminating in the reports of the Technical Commission on Nutrition¹⁶⁵ and the Mixed Committee on Nutrition in 1937.¹⁶⁶ It is obvious that as measured by any modern standard of adequate nutrition much of the world's population is subsisting on inadequate food. In terms of adequate food for every one, no food surplus has ever existed. In terms of dietary adequacy the world has never had enough to eat. So called overproduction and apparent surpluses have in reality been failures to secure adequate distribution. The recent United Nations Conference on Food and Agriculture¹⁶⁷ recognized that national and international agricultural policies must be directed toward obtaining a food supply adequate for health.

Although poverty is the principal cause of malnutrition, general economic improvement will not give every one an adequate diet. Faulty food distribution is the

most important contributory factor, and ignorance of the rules of good diet plus indifference to the consequences and bad dietary habits are the contributory underlying causes

Great Britain has shown that a national food policy based on nutritional adequacy can control malnutrition. Close control of food production, importation, and prices together with strict rationing and with a food distribution system planned with the assistance of nutrition experts with the goal of adequacy instead of profit has assured an individual availability of foods with the result that in spite of poorer living conditions incident to the war the infant mortality in 1942 was the lowest on record and health has been maintained at a high level with a decreased general death rate and a negligible incidence of deficiency diseases.

From the point of view of preventive medicine the problem of adequate nutrition is so different from other health problems that it requires a new approach. Its ramifications extend far into our whole economic structure. Such diverse problems as the control of crop production, farm machinery, manpower, food distribution, transportation, food preservation and processing, storage and food preparation as well as nutrition education and the diagnosis, prevention and treatment of deficiency diseases are all involved. It is obvious that problems of this range and magnitude cannot be solved by physicians, health officers or any other one agency alone. The first essential is close cooperation and intimate relations among a number of agencies including physicians and health officers.

A number of official and voluntary agencies in this country have been working on certain aspects of our nutrition problem for many years with little participation by physicians except from some health officers. The home economics and agriculture teachers in our high schools and colleges, the Agricultural Extension Service, the American Red Cross, the Children's Bureau of the Department of Labor and numerous other organizations have had continuing programs for a long time.

Many of our state health departments have established and maintained a small nutrition service at the state level with the assistance of the Children's Bureau. The attention here during peacetime was focused primarily on problems of maternal and child health, and an excellent start has been made. However, there are other population groups which also may be regarded as especially vulnerable from a nutritional point of view and to whom it is essential that attention also be given especially in wartime, for example school children, adolescents and workers in essential industries. In order to deal more effectively with these varied problems the regular nutrition activities of various government and voluntary agencies have been intensified, expanded and coordinated. A first meeting of representatives of these agencies was held in 1940 and in May 1941 President Roosevelt called the First National Nutritional Conference in Washington.¹⁰⁵

The National Nutrition Program was based on the recommendations of this conference, and coordination was obtained through the Nutrition Division of the Office of Defense Health and Welfare Services. These activities have now been incorporated into the Nutrition and Food Conservation Branch of the War Food Administration.

Regional nutritionists carry out the functions of this branch from the Food Distribution Administrative regional offices. On invitation these nutritionists work with state and local nutrition committees in planning and developing nutrition programs and projects. The most important accomplishment of this office has been the successful coordination of the nutrition program of various agencies, recognizing the place of each but centering attention on the common objective. It has shown that a coordinated program of this magnitude can be made to work in this country.

Nutrition committees have been formed in every state and in Hawaii and also are working on local nutrition problems in many counties, cities and local communities. In many instances there has been little or no participation by physicians or health officers in spite of invitations to medical societies and health departments to send representatives. The work of these committees has consisted mainly in the organization of nutrition classes, preparation and distribution of educational material, food demonstrations, victory gardens and home food preservation and it is expected that they will play an increasingly important role in war food programs through school lunch activities and nutrition in industry subcommittees. If properly developed they should become the local body through which all the food and nutrition problems of the community are attacked.

The ultimate purpose of a civilian wartime food program is to assure "enough to eat" to every one, so that the war may be fought with the utmost efficiency. The phrase "enough to eat" in its proper use must mean not only enough in quantity but also enough of all essential dietary elements. This means that the entire program must be planned on a sound technical nutritional basis with adequate control of distribution together with price control of those constituents of the nation's food supply necessary to secure dietary adequacy.

Failure to recognize the necessity for basing the control on nutritional adequacy, or half-way measures of control, defeat the whole purpose of the program and are worse than no control in that they create a false sense of dietary security, and a ration coupon becomes a symbol of unobtainable food rather than a guaranty of a fair share of an item necessary for the maintenance of health.

It is also essential that any such program take into account the greater physiologic needs of the 'vulnerable groups' in the population among the most important of these groups during war being the workers in war industries. Differential rationing by allotting more ration coupons to such groups would threaten the whole rationing structure because of difficulties in administration and the great difficulty in assessing the actual needs of the individual based on his special requirements. In general the most practicable solution is to develop feeding facilities within each industrial plant which can supply an adequate midshift meal to every employee without requiring ration coupons. In a few industries operating under special conditions of isolation from the usual food supply it may be necessary to supply extra food to the entire establishment. Here the allocation is made to the group and not to the individual. Rare exceptions such as sheep herders may require special allocation.

The aspect of industrial nutrition which involves the community can be attacked by the local nutrition committee. Infant feeding should be regarded as one aspect of a properly developed industrial hygiene program. It should be approached through the plant medical officer or safety director after the plant management has agreed to the program.

At the federal level the War Food Administration works closely with the Industrial Hygiene Division of the National Institute of Health of the United States Public Health Service. At the state level, when state health departments have industrial hygiene officers they should be one of the points of contact with the plant, using the advice and assistance of the local and state nutrition committee. Because of the scope and importance of the industrial nutrition problem the War Food Administration has appointed regional nutrition representatives to work with state and local committees as well as health officers and plant officials.

On request from industrial plants, industrial nutritionists assist in planning employee feeding and nutri-

to include an effort to attain the best possible level of health which is unknown in the absence of good nutrition.

The fact that malnutrition and deficiency diseases usually appear insignificant in mortality and morbidity tables does not reflect the real importance of nutrition in our national health. Although good nutrition does not guarantee good health, poor nutrition can and often does contribute to mortality from other primary causes, while optimum nutrition can contribute to optimum health.

The health officer and physician can help determine the prevalence of malnutrition and relate nutrition problems to other public health and medical problems. Some of the more important activities for health departments in developing this field in collaborating with existing programs were recently proposed by Sebrell and Wilkins¹⁶⁹ as follows:

STATE HEALTH DEPARTMENT ACTIVITIES

1 Collect information and do appraisals on the incidence and types of deficiency diseases and on food habits in geographical areas and population groups, especially children, pregnant and lactating women and industrial workers. Even small samplings are of value in pointing the way to more comprehensive appraisals.

2 Offer assistance in the diagnosis of nutritional deficiencies. Here is a health department service which is in line with sound public health principles and which will strengthen the work of other agencies in this field. At the same time the efforts of other agencies will contribute greatly to creating a demand for this type of service.

3 Prepare and distribute simple attractive literature dealing with state nutrition problems. Such literature should be prepared with a full knowledge of all other nutrition literature being used by other agencies in order that duplication and conflicting viewpoints may be avoided.

4 Cooperate actively with other agencies dealing with different aspects of the nutrition problem. Offer the specialized services of the health department to other agencies to help them in dealing with their particular phases of nutrition.

5 Take an active part in the work of the state nutrition committee.

6 Offer information, consultation, guidance and encouragement to local health departments in developing local nutrition programs and in cooperating with the local nutrition committees.

7 Promote staff education in nutrition, including facilities for professional education in public health nutrition, and education of county and city health department personnel in nutrition activities.

8 Assist in sponsoring conferences and refresher courses in nutrition and related fields for public health and school personnel. During the past three summers nine such cooperatively sponsored six week conferences have been held in one state. Similar projects have been successfully carried out in several other states.

9 Active participation of nutritionists in the public health nursing and dental hygiene program, in well child clinics, in school health programs and in other activities of the maternal and child health division.

10 Include nutrition in the industrial hygiene program not only by nutrition education in the plant, but also by improving plant feeding facilities and the nutritional quality of the meals served.

11 Cooperate with and assist the state food distribution administrator in locating and meeting local food problems.

12 Take an interest in school lunch programs. The United States Public Health Service can consider requests for nutritionists for these programs under title VI funds if recommended.

TABLE 11—Necessary Foods

- 1 Green and yellow vegetables, some raw some cooked frozen or canned
 - 2 Oranges, tomatoes, grapefruit or raw cabbage or salad greens
 - 3 Potatoes and other vegetables and fruits raw, dried, cooked, frozen or canned
 - 4 Milk and milk products fluid evaporated, dried milk or cheese
 - 5 Meat poultry, fish or eggs or dried beans, peas, nuts or peanut butter
 - 6 Bread flour and cereals whole grain or enriched or restored
 - 7 Butter and fortified margarine (with added vitamin A) 'Eat some food from each group every day'
- "In addition to the basic 7 eat any other foods you want"

Further instructions in order to cover possible wartime shortages are as follows:

If scarce in	Use more from
Group 2	Group 1, 3
Group 4	Group 1, 5, 6
Group 5 (meats)	Group 4, 5 (eggs)
Group 7	Group 1, 4

tion education programs and in handling applications for essential equipment and food. They also work with labor groups in promoting better eating habits.

In many states industrial nutrition subcommittees have been organized under the state nutrition committee. The representative of the health department should work with these subcommittees, which include industrial physicians, caterers, representatives of labor, plant management and other interested groups.

Nutrition committees throughout the country are constantly striving to improve the public knowledge of nutrition and to develop better food habits. Food shortages make these activities more important than ever. This education is based on food groups designed to yield nutritional adequacy with considerable latitude in the choice of food items. The recommendation is a type diet which for application requires local adaptation to specific items. The necessary foods are listed in seven groups (table 11).

Physicians and health officers should assist in the promotion of sound nutrition education as well as in promoting good food programs designed to improve nutrition. The health officer has both an opportunity and an obligation here in preventive medicine which cannot be performed as well by any other group. The concept of the prevention of disease must be enlarged

169 Sebrell W. H., and Wilkins Walter. The Role of the Health Department in the National Nutrition Program, Pub. Health Pers. 54, 803 (May 21) 1943.

and requested through local and state health departments. Under rationing we should give more attention than ever to the adequacy of the meals our children get at school.

LOCAL HEALTH DEPARTMENT ACTIVITIES

1. Learn what other agencies have done and are doing within the area.
2. Affiliate with the local nutrition committee.
3. Study the nutritional status and needs of the area from medical and public health angles and help orient other agencies in this regard.
4. Distribute and interpret nutrition teaching material, especially material which deals primarily with local problems.
5. Have a planned program for staff education in nutrition within the department or in cooperation with other agencies.
6. Exert a stabilizing influence and interpret sound nutrition practices to the public, avoiding fads and extremes.
7. Interpret local nutritional conditions to the public through talks, newspaper articles, radio programs and so on.
8. Make an effort to increase the interest of local medical and dental professions in local nutrition problems and practical solutions.
9. Develop nutrition educational facilities for patients who attend public health clinics. In some places it may be advisable to establish clinics to deal primarily with nutrition problems.
10. Develop and maintain a movie, film strip and slide library on nutrition and related subjects.
11. Encourage public eating places to serve food of good nutritional value and to prepare their foods in such a way as to conserve vitamins and minerals. This might be started as a consultation service.
12. Encourage civic clubs to sponsor programs which either directly or indirectly will improve the nutrition status of groups within the community.
13. Advise and sponsor feeding facilities in connection with child day care programs.
14. Stress nutrition in school health programs.
 - (a) Cooperate with teachers-parent-teachers associations and lunchroom managers in improving school lunches.
 - (b) Sponsor cooperative school lunch programs.
 - (c) Encourage the use of simple, wholesome, home prepared foods in lunchboxes rather than the use of store bought snacks.
 - (d) Watch for and stress nutritional deficiencies in physical examination of school and preschool children.
 - (e) When practical conduct or sponsor demonstrations with school children showing results of improved nutrition (properly integrated with other health habits).
 - (f) Sponsor 'sampling surveys' of school children for nutritional status. If possible get local medical and dental societies to cooperate.

From a national point of view the state of nutrition of a considerable part of the population of this country is unsatisfactory and has been so for many years. Whether even this present state of nutrition can be maintained in the face of the present food situation depends on the efficiency with which we produce, distribute and utilize our food supplies. The signs and symptoms of malnutrition are often overlooked or attributed to other causes. Gross deficiency disease still exists and the relationship of nutrition to other health problems is not common knowledge as it should be. Poor methods of using preserving and preparing foods both in homes and in public eating places are responsible for tremendous losses in food values. Even in the face of food shortages there is as yet little tendency to conserve and use every bit of edible food. The uses of alternate foods when shortages exist is little appreciated. A shortage in beef results in a public clamor to satisfy the palate although physiologic needs can be met easily from other food sources without difficulty.

There is probably more public interest in nutrition and food today than ever before. Physicians and health

officers can play an enormously important part in the national effort to improve nutrition by guiding this interest along sound lines. Too often the busy physician finds it easier to prescribe a vitamin pill than to investigate food habits and recommend dietary changes. Health officers need to become acquainted with the nutrition work being done by other agencies and have their staff members take their proper place in the nutrition program after they have obtained a background of knowledge of the work being done by other organizations.

We have an unparalleled opportunity in the field of preventive medicine. If agriculture is to be based on the nutritional needs of the population health and medical authorities should determine what those needs are. Satisfactory nutrition depends on health and agricultural authorities working together. Agriculture up to now has had to assume the major portion of the burden of solving our nutritional problems. It is past time for medical and health authorities to assume their share of the responsibility.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
REPORT
AUSTIN E. SMITH, M.D., Secretary

NOMENCLATURE OF ENDOCRINE PREPARATIONS

Considerable progress has been made in the last few years on the development of potent endocrine preparations for clinical purposes. The standardization of these products has been significantly improved of late and promises to be established on a satisfactory basis. Nevertheless there is still confusion in the minds of physicians regarding the identity of many of these products, their sources and potencies. One of the factors most responsible for this unsettled state is the retention of proprietary terms for these products. The Council has made several appeals for a scientific nomenclature and has taken numerous steps in this direction so that therapy with endocrine preparations would not necessitate an intimate knowledge of the detailed lists of products. In the 1942 edition of *Glandular Physiology and Therapy* the chapter on 'Present Status of Commercial Endocrine Preparations' discussed the therapeutic value of the various endocrine preparations together with a listing of the products accepted by the Council. No attempt was made, however, to note the proprietary names of other than products accepted by the Council except by their scientific terminology. The Council now considers it advisable to furnish physicians with the names and synonyms of these endocrine preparations which have been shown to have therapeutic effects. The present report was prepared therefore in order to enable physicians to clarify in their minds the nature of the various products, both proprietary and nonproprietary, together with the synonyms basis of standardization and sources. The Council reserves the privilege of omitting from this list those preparations which are acknowledged by authorities to be of little value in endocrine therapy because of their unscientific nature, lack of sufficient potency or other evidence indicating little rationale for their use. The reader is referred to an article by W. A. Schonfeld (*New York State J. Med.* 42:1538 [Aug. 15] 1942) who in writing a somewhat similar article has included preparations which the Council does not see fit to list for the reasons mentioned. In the present report the reader is advised that preparations are being omitted which are marketed by firms which have no products accepted by the Council in order to eliminate an excessive amount of effort and time in examining these multitudinous products. Such omissions do not necessarily imply a disapproval of certain of these products. The fact that

products are included in the appended list is, on the other hand, no indication that the Council approves of all of them. As a matter of fact, some of these products have been rejected by the Council. The reader is referred to chapter XXXI of *Glandular Physiology and Therapy* (13th Journal, Oct 4, 1941 p 1175) for brief discussions on the actions and uses of some of the preparations described in the following list.

[Note—Products marked with an asterisk have been accepted by the Council for inclusion in New and Nonofficial Remedies.]

THYROID GLAND

DESSICATED THYROID

Source: Obtained from domesticated animals that are used for food by man. Assay Chemical—U S P standard requires from 0.17% to 0.23% of iodine in thyroid combination.

PRODUCT AND FIRM

- *Thyroid U S P. Marketed by eight or more firms.
- Thyroid Implants—iodine 0.3% assayed 50% above U S P. Parke Davis.
- Thyroid Tablets—iodine 0.4% (net wt) 5 grains equal 2 grains U S P. Burroughs Wellcome.
- Note: Avoid unstandardized products.

THYRONIN (Natural)

Source: Active principle obtained from thyroid gland. Assay Chemical—U S P requires not less than 64% iodine in thyroxine molecule.

PRODUCT AND FIRM

- *Thyroxin (crystals, intravenous). Squibb.

THYRONIN (Synthetic)

PRODUCT AND FIRM

- *Synthetic Thyroxin (intravenous and oral). Hoffmann-La Roche.

THYRONIN FRACTION

Source: Disodium salt of thyroxine. Assay Chemical—contains stated weight of thyroxine.

PRODUCT AND FIRM

- *Tablets Thyroxin Fraction (oral). Squibb.

PARATHYROID HORMONE

PARATHORMON

Source: Animal parathyroid gland. Assay U S P units.

PRODUCT AND FIRM

- *Parathyroid Extract. Lilly.
- *Parathyroid Hormone. Squibb.
- *Pituitin. Parke Davis.

ADRENAL CORTEX

ADRENAL CORTICAL EXTRACT

Source: Adrenal gland of animals. Assay Biologic units (1 cc of extract is derived from 40 Gm of fresh gland).

PRODUCT AND FIRM

- *Adrenal Cortex Extract. Upjohn.
- Adrenal Cortex Extract. Wilson Laboratories.
- Cortin. Roche Organon.
- Eschatin. Parke, Davis.

DESOXYCORTICOSTERONE ACETATE

Source: Synthetic. Assay Weight.

PRODUCT AND FIRM

- Cortate. Schering.
- Doca. Roche Organon.
- Percorten. Ciba.

ADRENAL MEDULLA

EPINEPHRINE

Source: Active principle of adrenal medulla, natural or synthetic (levorotatory). Assay Chemical—U S P standards.

PRODUCT AND FIRM

(Prepared for hypodermic, intravenous and oral medication)

- *Suprarenalin. Armour.
- *Adrenalin. Parke, Davis.
- *Epinephrine. Upjohn, Wilson and other firms.
- *Suprarenin. Winthrop.

SOLUTION OF EPINEPHRINE HYDROCHLORIDE U S P 1,000

Composition: Epinephrine in distilled H₂O and hydrochloric acid—1,000.

- *Products: Marketed by nine or more firms.

SOLUTION OF EPINEPHRINE HYDROCHLORIDE U S P 1,100

Composition: 1 part of epinephrine hydrochloride U S P in 100 parts of isotonic solution of sodium chloride.

1 See also Activated Sterols. Source: Ergosterol, irradiated product. Viosterol in Oil. See list in N N R Hytakerol (dihydroxycholesterol, formerly known as A T 10), Winthrop.

PRODUCT AND FIRM

- *Suprarenin Solution 1 100. Armour.
- *Solution of Adrenalin Chloride 1 100. Parke, Davis.

SUSPENSION OF EPINEPHRINE IN OIL 1 500

Composition: A 0.2% suspension, containing 1 part epinephrine U S P to 500 parts vegetable oil.

PRODUCT AND FIRM

- *Epinephrine in Oil 1 500. Endo Products, Lakeside, Smith-Dorsey, Squibb.
- *Adrenalin in Oil 1 500. Parke, Davis.

PANCREAS

INSULIN (Crystalline)

Source: Beef and pork pancreas. Assay Biologic—solution of zinc insulin crystals standardized as follows: 1 mg contains 22 insulin units as defined by Insulin Committee of University of Toronto.

PRODUCT AND FIRM

- *Insulin, U 20, U 40, U 100. Sharp & Dohme.
- *Insulin, U 20, U 40, U 80, U 100. Squibb.
- *Iletin, U 20, U 40, U 80, U 100. Lilly.

PROTAMINE ZINC INSULIN

Composition: A suspension of the precipitate of insulin, protamine and zinc in buffered solution. Assay: As above, with additional chemical assay.

PRODUCT AND FIRM

- *Protamine Zinc Insulin, U 40, U 80. Sharp & Dohme, Squibb.
- *Protamine Zinc and Iletin, U 40, U 80. Lilly.
- Note: Standard label colors: U 20, yellow; U 40, red; U 80, green; U 100, orange.

ESTROGENS (CRYSTALLINE)

ESTRONE—Theelin—Ketoxydroxyestrin

Source: Urine of stallions and pregnant mares. Assay International standard (0.0001 mg equals 1 international unit).

PRODUCT AND FIRM

- *Estrone in Oil. Abbott, Lilly.
- *Estrone Suppositories. Abbott, Lilly.
- Estrone Aqueous Suspension. Abbott.
- *Theelin in Oil. Parke, Davis.
- *Theelin Suppositories. Parke, Davis.
- Theelin Aqueous Suspension. Parke, Davis.

ESTRIOL—Theelol—Trihydroxyestrin

Source: Urine of pregnant women. Assay Weight.

PRODUCT AND FIRM

- *Estriol Capsules. Abbott, Lilly.
- *Theelol Capsules. Parke, Davis.

ESTRADIOL—Dihydroxyestrin

Source: Chemical modification of estrone from the urine of stallions and pregnant mares. Assay Weight or biologic units.

PRODUCT AND FIRM

- Dimenformon Ointment. Roche Organon.
- Dimenformon Tablets. Roche Organon.

COUNCIL STANDARDS AND MEDICAL ADVERTISING

Among the most important steps for the advancement in the United States of the practice of scientific therapy was the establishment of the Council on Pharmacy and Chemistry by the American Medical Association. The Council on Pharmacy and Chemistry was organized to protect the medical profession and the public against fraud, undesirable secrecy and objectionable advertising in connection with proprietary medicinal articles. A proprietary article means any chemical, drug or similar preparation used in the treatment of disease and protected against free competition as to name, product, composition or process of manufacture by secrecy, patent, copyright or other means. Notwithstanding the wholly laudable character of these functions, the creation of the Council was met by a furor of opposition from manufacturers, salesmen and the venal medical press which derived from this unsavory business profits tainted by their origin from the helpless sick and the dying. Patients must depend on their doctors for the choice of remedies. Doctors depended then on the information that came to them in the pages of medical publications and on information derived from detail men. Only too often even those pages of periodicals devoted to allegedly scientific contributions could be influenced if not purchased by the advertising that appeared in the same issue. No wonder that the establishment of a council of physicians, pharmacologists, chemists, physiologists and other qualified scientists to sift truth from falsehood and to give physicians a dependable source of information on new and nonofficial remedies should have elicited a shrieking and a moaning and a groaning from those who saw in its functioning their impending dissolution.

In almost thirty-five years that have passed since the Council came upon the scene, its results have justified the far sighted efforts of Philip Mills Jones, Frank Billings, George H. Simmons, Reid Hunt, Lafayette Mendel, Torald Sollmann and other medical and basic science leaders who gave so freely of their

time and then wisdom to its work. Again and again the medical leaders of foreign nations have written in envy of the ability of the Council to achieve the results it seeks. The subsequent creation of Councils on Foods and Nutrition and on Physical Therapy has been an indication of the approval of the House of Delegates.

In the years that have passed, more and more manufacturers of pharmaceutical preparations have given their collaboration and support to the work of the Council on Pharmacy and Chemistry. Many medical schools in their teaching of therapeutics limit themselves to the products listed in *Useful Drugs*. The book *New and Nonofficial Remedies*, a list of the preparations investigated and accepted by the Council, is increasingly used as a reference in medical schools and hospitals. The new legislation which controls foods and drugs developed from national acceptance of the principles so long maintained by the Council, no longer is it possible to launch a new remedy on the American public without previous controlled clinical testing. Such governmental control is, however, concerned only with harmlessness, and not with efficacy or advertising of the product. All the more need, therefore, for the work of the Council.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, under the direction of the Board of Trustees limits its acceptance of advertising to products that have been accepted by the Council. All advertising for Council-accepted products is submitted to the Council on Pharmacy and Chemistry for consideration prior to publication. Most of the state medical journals and several independent medical journals also restrict their acceptances of advertising similarly. Such support is necessary to maintain the strength of the Council. Formerly some of the state medical journals were the private property of physicians, publishers or corporations that had founded them. They were conducted largely for financial gain or personal prestige. Gradually ownership changed, today in most instances these publications are the property of the state medical associations which publish them.

Outside the periodicals published by medical organizations are some which do not limit their acceptance of advertising in any easily apparent way. Their pages are replete with the announcements of remedies that have not met the criteria of scientific evaluation. Conspicuous examples of this type are the throw-away publications, such as *Medical Economics* and *Modern Medicine*, sent free to physicians because their support comes from the publication of advertising which could not gain entrance into periodicals of recognized scientific origin and merit.

The journals of two state medical societies—Illinois and New York—have been conspicuous almost from the first in their insistence on the profits to be derived from the publication of advertisements of unaccepted products. For a brief period the *New York State Journal of Medicine* agreed to abide by scientific therapy, apparently

the insistence of the business office ultimately prevailed, that periodical is today among those counted as lost before the altar of those who give their faith to scientific therapy.

In 1913 the Board of Trustees of the American Medical Association, in its desire to aid and support the work of the Council on Pharmacy and Chemistry and to aid those medical periodicals which wished to enlist themselves in this righteous cause created the Cooperative Medical Advertising Bureau. Year by year the reports of the Bureau have appeared and have indicated the extent to which the Bureau has been helpful in securing advertising for the state medical journals and increasing their income. Recently there seems to have been a lessening of the careful scrutiny of advertising copy that is necessary in limiting advertising strictly to Council-accepted products. In the past month, for instance, the *Pennsylvania Medical Journal* has carried announcements of perandren and metandren male sex hormones which have not been accepted and of prinine, a vasoconstrictor used for nasal inhalation. The *New England Journal of Medicine* carried one for teriosate, which is a mixture used against anemia. *California and Western Medicine* in the July issue alone published advertisements for six nonaccepted products. Indeed, almost any issue of any journal may have one or more advertisements that do not meet Council Standards. The September issue of the *Southern Medical Journal* carries advertisements for more than twenty unaccepted preparations, and the Illinois and New York journals continue to be veritable directories of unestablished and unscientific therapy.

As long as any considerable part of the medical profession contributes to extending the blight of the falsely exploited proprietary medicine the battle for scientific therapy remains difficult. In any war the most dangerous attack is the attack from the rear. The threat most difficult to meet is that from those who should be presumed to be friends. The time should long since have passed when leaders of medical organizations consent to permit the exploiters of unestablished proprietary remedies to pay the bulk of printing and publishing bills of the medical journals that are supposed to represent scientific medicine. Can the physicians of Illinois and New York and the representatives of a few states who are urging a breakdown of the Council standards believe that the business managers of their periodicals are better equipped to judge what is good in materia medica and therapeutics than is the Council on Pharmacy and Chemistry? Fortunately for American medicine the vast majority of the profession has not accepted that point of view. The governing bodies of the medical societies of Illinois and New York and the Councils and boards of trustees of the other medical societies which are being urged by business managers to depart from the standards of the Council might well give more consideration to their responsibility to scientific medicine. The good name

and prestige of American medicine have come from its support of scientific remedies and ethical practice, from its condemnation of fraudulent and unscientific nostrums and of commercialized medicine. That good name gives us strength before the bar of public opinion where the point of view of scientific medicine needs to prevail. Let us keep the good name unsullied; its value is far above that of jewels or gold.

REACTIONS FOLLOWING SPINAL PUNCTURE

Reactions have been variously reported as occurring in 17 to 40 per cent of patients after lumbar puncture. The syndrome includes headache accompanied in severe cases by vertigo, nausea and vomiting. The most characteristic feature of this headache is the prompt relief that ensues when the patient lies down, and return of the headache when he sits up. The headache may be transitory, lasting one or two hours, moderate, terminating in one or two days, or severe, lasting six or more days. Sicard and others suggested that the headache was due to leakage of the cerebrospinal fluid into the epidural space through the defect in the dura left by the puncturing needle. The cerebrospinal fluid in a closed sac forms a pad for the brain and the spinal cord. At the base of the brain this pad acts as a cushion or water bed. MacRobert¹ argued that the cushion is absent when the patient sits up and the weight of a good part of the brain is suddenly imparted through the pons to the communicating plexus of veins. The blood about to leave the skull is impeded and is forced to turn back and travel by other crowded pathways. The resulting congestion causes a sudden rise of venous pressure. The relief of headache when the patient lies down is due to the fall of pressure when the weight is removed from the plexus of veins resting on the clivus of the occipital bone. The proponents of the leakage theory urged that the patient be confined to bed with the head lowered for twenty-four to forty-eight hours. Of the 30 patients thus treated, MacRobert records the occurrence of severe headache in 12 (40 per cent). Jacobaeus and Frumerie² and later Nelson³ found that there was a significant fall in the spinal fluid pressure between the time of the spinal puncture and the onset of the headache, suggesting reduction in the volume of the blood, probably through leakage. Nelson developed an ingenious method of plugging the puncture hole in the meninges with a strand of catgut. Of 102 cases in which this was practiced, typical postpuncture reaction developed in only 5 (4.9 per cent). Of 92 cases in which spinal

2 Jacobaeus, H. C. and Frumerie, K. A Study of the Leakage of the Spinal Fluid After Lumbar Puncture and Its Treatment. *Arch. Surg.* 58: 10, 1921.

3 Nelson, M. O. Postpuncture Headache. A Clinical and Experimental Study of the Cause and Prevention. *Arch. Dis.* 21: 11 (April) 1921.

puncture was concurrently made in the usual manner, typical postpuncture reaction developed in 16 (17.4 per cent)

The leakage theory and the theory of meningeal irritation have been questioned recently by observers who have found that patients who were not put to bed after the puncture had less reaction than those who were treated by bed rest. Adler⁴ argued that a patient in the upright position should have greater leakage and therefore more severe headache. Blau⁵ reported that 21.2 per cent of patients who rested in the clinic and at home had reactions of a severe nature. Of those who left the clinic immediately but rested all day at home 21.7 per cent had severe reactions, but of those who did not rest at all only 6.4 per cent reacted severely. He concludes that the best method of preventing postpuncture reactions is the use of a fine needle and keeping the patient active for a considerable time after the puncture. Adler encouraged his patients to stay erect as long as possible after the puncture. Out of a group of 108 patients 14 (13 per cent) had a moderate or severe reaction. Of 10 men who went to bed immediately after the puncture, 7 (70 per cent) had moderate to severe reaction. Of 20 men who went to bed eight hours after the puncture, 2 (10 per cent) had slight and 2 (10 per cent) mild reactions, none had either moderate or severe reactions. Of 38 men who went to bed six hours after the puncture, only 2 (5 per cent) had severe or moderate headache. Adler therefore believes that the leakage and the meningeal irritation theories do not explain the reaction. He concludes that the cause of the headache is increased intracranial hypertension due to reaction of the choroid plexus caused by emotion. He points to the fact that Kulchar and King⁶ were able to reduce the incidence of typical postpuncture headache from 25.5 per cent to 13.5 per cent in 105 patients by the administration of 3 grains of sodium amytal by mouth before puncture. Schube and Le Drew⁷ reported a diminution in the incidence of reactions following lumbar puncture by administration of 3 grains of sodium amytal. Adler found a definite relationship between constitutional inadequacy and headache. Davenport⁸ likewise suggests that lack of physical stamina and increased suggestibility, as evidenced in the higher incidence of reactions among females and Puerto Ricans in his large series, are factors. Adler believes that the predominant factors in the causation of postpuncture headache are the constitutional make-up of the patient and psychogenic influences.

Consideration of the several theories advanced and of the contradictory facts presented suggests that further studies will be required to elucidate the mechanism of the postpuncture headache and its successful prevention.

Current Comment

THE EPIDEMIOLOGY OF SCARLET FEVER

An epidemic disease can be most satisfactorily investigated by studying the community in which the outbreak occurs throughout the preepidemic, epidemic and postepidemic periods. Such an investigation was carried out near Iasi (or Jassy) in Rumania in 1936 under the auspices of the International Health Division of the Rockefeller Foundation and the Iasi Institute of Hygiene.¹ The city in the province of Oltanea had a population of about 100,000. The field work was done in the villages surrounding the city. The area was primarily agricultural, the inhabitants living for the most part in small villages and proceeding to their farm work each day in the surrounding countryside. The studies demonstrated a rough semilogarithmic relationship between the degree of latitude and the incidence of scarlet fever in that latitude. It has been suggested that this relationship may be due both to climatic conditions and to a lower susceptibility of those races which populate the tropical regions. The studies showed that the streptococcus flora of a community during nonepidemic periods includes many different strains, almost constantly changing their relative proportions. Persons up to 20 years of age are more frequently carriers than are adults. The types of streptococci which are prominent in causing scarlet fever one year may gradually assume an insignificant role and be replaced by other types. During epidemics a single type is generally responsible but this may vary, depending on whether an outbreak occurs in a community free from scarlet fever or is superimposed on previously existent endemic disease. A type of streptococcus which causes scarlet fever may also cause other forms of streptococcal illness. The types of streptococci most frequently recovered from persons with scarlet fever and other streptococcal diseases are those most commonly found in normal carriers in the same community. This suggests that the pathogenesis may be related to the degree of distribution of the organisms throughout the community. The number of cases of scarlet fever which occur is related to the carrier rate for the epidemic type. The distribution of cases of scarlet fever by age coincides with the age distribution of positive Dick tests, except that the peak for the former is with children from 5 to 9 years old and for the latter from 1 to 4 years old. Antitoxic immunity is accepted, and, with few exceptions, Dick negative persons are immune to the clinical syndrome of scarlet fever. Antibacterial immunity may also be a factor. The principal conclusion from this study is that the amount of illness caused at any one time by a given strain of streptococcus

is determined by three factors—the current pathogenic ability of the strain, the degree of dispersal throughout the community and the specific immune status of the population. These factors are all labile and their constant change accounts for the variations with time in the amount of streptococcal disease. Following the outbreak of war in Europe it was necessary to remove the collected material to New York and to complete the studies in the laboratories of the International Health Division there. This is of course, only one example of the tremendously disruptive force of war on medical research.

HAIR LACQUER PADS—A WARNING

Information has come to the office of THE JOURNAL to the effect that certain hair lacquer pads widely used by women throughout the United States to make the hair conform to recent styling or "up-do," have been causing dermatitis or severe inflammations of the skin around the back of the neck and ears. Cases have come to the attention of physicians in many cities. The Food and Drug Administration immediately on notification made a preliminary investigation which, according to reports reaching THE JOURNAL, indicates that the irritative action results from a change in the formula of manufacture of the products under investigation by the inclusion of a new gum. It may take some time to identify this ingredient accurately. With the usual alertness and efficiency that have characterized its activities the Food and Drug Administration has issued a request for the recalling of hair lacquer pads manufactured by Hubere Cosmetics of Chicago and of the Parfait Powder Puff Company, an Illinois corporation. Under the circumstances, women will do well to discontinue the use of these hair lacquer pads until their harmlessness has been established.

ANTHIOMALINE IN CLINICAL MEDICINE

Anthiomaline is lithium antimony (trivalent) thiomalate prepared as a 6 per cent solution, 1 cc of which contains about 0.01 Gm of antimony. An analysis of the extensive pharmacologic and experimental studies has just become available.¹ The drug has been employed therapeutically in venereal lymphogranuloma, granuloma inguinale, schistosomiasis, leishmaniasis, filariasis, trypanosomiasis, febrile jaundice, multiple sclerosis and trachoma. Therapeutic dosage depends on the disease to be treated, as do some of the toxic reactions to the drug. Its approximate range of therapeutic effectiveness was indicated by early experiences with venereal lymphogranuloma. It has been proposed to begin with 60 mg injected intramuscularly and to increase the dose of the single injections to a possible maximum of 300 mg until a total dose of between 2 and 4 Gm has been reached. Injections ordinarily are given three times a week and repetition is advisable after an interval of several weeks. The maximum dose for a single injection may be determined by the appearance of rheumatoid pains, which constitute the most widely

observed toxic reaction. The pains may be localized or general, they appear several hours after injection and they usually last twenty-four hours and occasionally longer. Painful swellings at the site of the injection sometimes occur. Salivation, retching, vomiting and abdominal pains have been observed. Slight fever, headache, thirst and fatigue may also appear in the course of treatment. Venereal lymphogranuloma is the condition in which anthiomaline has been used most extensively—some 250 cases having been recorded in the literature. Excellent results were obtained in 35 to 75 per cent and failures have been encountered in from 10 to 25 per cent of the patients treated. Experience with granuloma inguinale has been too scanty to warrant conclusions, although the results appear promising. Anthiomaline treatment of filariasis on a small number of patients has on the whole been disappointing. Good results have been uniformly reported with the use of this drug in more than 130 cases of genitourinary schistosomiasis. The efficacy of anthiomaline in cases of leishmaniasis is extremely doubtful. Thirty-three cases of trypanosomiasis have been treated with a combination of moranyl and anthiomaline with consequent sterilization of lymph and blood and reports of cure of fifteen months' duration in 17 cases. From the information available it may be concluded that anthiomaline has a considerable variety of therapeutic usefulness and a sufficiently low toxicity to warrant its further clinical trial.

HEALTH AND THE "VICTORY CORPS"

The United States Office of Education, sponsoring the Victory Corps in high schools, has published the proceedings of a committee of physicians and educators convened by the Office of Education to outline preparation of teachers for the program of physical fitness through health education.¹ The shortage of school personnel for health education led the United States Commissioner of Education to consider the possibility of giving supplementary training to science teachers and to teachers of home economics and physical education. The committee² met in May and formulated standards which teachers should meet if they are to be expected to function in the health education program. These standards, in general, indicate that persons having medical knowledge such as doctors, are not usually equipped pedagogically and vice versa. The findings and recommendations of the committee which should be of interest to physicians and educators, and especially to physicians serving as public health officials in school health programs or as members of boards of education are available in a reprint³ from the official biweekly publication of the United States Office of Education, "Education for Victory." Inquiry should be addressed to the United States Office of Education, Federal Security Agency, Washington, D. C.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession

ARMY

AVIATION MEDICAL EXAMINERS

Graduation exercises were held at the School of Aviation Medicine, Randolph Field, Texas, on August 26 following completion of the course for aviation medical examiners. The didactic portion of the course was conducted at the School of Aviation Medicine, Randolph Field, Texas and the practical portion of the course at the three army air forces classification centers. The list of students graduating follows:

ALABAMA

James P. Collier, Major, Tuscaloosa
Albert H. Green, Major, Birmingham
Liras A. Kaiser, Major, Montgomery
James H. Means, Captain, Anniston
David D. Smith, Captain, Birmingham

ARIZONA

John S. Miller, Major, Tucson
William G. Shultz, Major, Tucson

ARKANSAS

Barnett P. Briggs, Captain, Little Rock

CALIFORNIA

Charles Benninger Jr., Captain, Oroville
Henry C. Bernstein, Captain, San Francisco
Norman C. Fox, 1st Lieut., San Bruno
William A. Gannon, 1st Lieut., Pasadena
Herbert Greenwood, Major, Oakland
Millard E. Gump, Major, Oakland
Gordon C. Hall, 1st Lieut., Soledad
Ronald L. Hughes, 1st Lieut., Los Angeles
Jesse J. Iverson, 1st Lieut., San Francisco
Maxwell S. Kassel, 1st Lieut., Hondo
Frederick G. Kirby, 1st Lieut., Los Angeles
Edward A. Kirz, 1st Lieut., Butte Meadows
Arthur L. Kobal, 1st Lieut., Los Angeles
Donald O. McGowan, Major, Los Angeles
Newell L. Moore, Major, Santa Ana
Ralph E. Netzeley, Captain, Pasadena
Maurice J. Regan, 1st Lieut., Los Angeles
Frederick G. Reynolds, Captain, Los Angeles
George H. Rue, 1st Lieut., Riverside
Lawrence A. Solberg, 1st Lieut., Kerman
Milo K. Tedstrom, Major, Santa Ana
George E. Webster, 1st Lieut., Inglewood
Harris R. Wilson, Captain, Modesto

COLORADO

Robert K. Dixon, Major, Denver
Bryce D. Smith, 1st Lieut., Denver

CONNECTICUT

George A. Burnie, 1st Lieut., Danbury
George R. Eckert, 1st Lieut., Danbury
Ronald H. Kettle, Major, Norwich
Royal A. Meyers, Major, Watertown
Victor G. H. Wallace, Major, Darien

DELAWARE

Constance A. D'Alonzo, 1st Lieut., Wilmington

DISTRICT OF COLUMBIA

DOCTORS OPERATE UNDER SHELLFIRE

Following is a dispatch as printed in the Chicago Sun, Sep
tember 24, from the United Nations Headquarters in North
Africa

Three delicate operations of brain surgery were performed
successfully in a tent among the sand dunes of Salerno during
the critical days when the Germans had the entire Fifth Army
bridgehead under artillery fire it was revealed today

Lieut Col Paul K Sauer of New York Hospital took his
contingent ashore amid a rain of German lead

Exhausted by two days and nights of bombing, strafing and
mortar fire the men of the evacuation hospital finally organ
ized their scattered equipment and spent all night setting up
portable operating rooms and tent walled wards on a field not
far inland Then the tired staff began a twenty-four hour
schedule of operations and treatment

Major Howard A Patterson of New York, former surgeon
at Roosevelt Hospital and a veteran of the Tunisian campaign
led his surgical staff in a round the clock schedule, with three
teams working in succession on never empty operating tables

Nurses were not due to be landed for several days, so the
hospital's enlisted men donned operating gowns and sterilized
masks and worked long hot hours in operating tents Many
had no more than two hours' sleep in the first three days

Casualties that piled up during the first week of the cam
paign made expansion necessary so a surgeon was added and
then tents from a medical battalion Abdominal punctures head
wounds, fractures and burns tormented the bulk of the hospital
cases

COLONEL DABNEY AWARDED LEGION OF MERIT

Col Albert S Dabney M C U S Army, who recently
relinquished his duties as assistant commandant of the Medical
Field Service School Carlisle Barracks, Pennsylvania, was
awarded on September 15 the Legion of Merit for meritorious
conduct and outstanding service. The presentation was made
by Brig Gen Addison D Davis commandant of the school
It read in part as follows

Col Albert S Dabney, M C U S Army For excep
tionally meritorious conduct in the performance of outstanding
service. From the beginning of the emergency until the end
of 1941 he has been director of the Medical Department Equip
ment Laboratory, where by his conspicuous energy and ability
he developed many new major articles of equipment needed
by the Medical Department for war Since Jan 1 1942 as
assistant commandant of the Medical Field Service School he
has had immediate charge of training approximately 14,000
Medical Department officers and officer candidates His careful
supervision of their instruction has been a contributing factor
and his knowledge have resulted in giving them a better
acquaintance of their duties and in the successful execution of
the success of the United States in the present war

With twenty-seven years of service to his credit, Colonel Dabney already holds decorations from the American, British, French and Russian governments, as well as numerous other military ribbons. He was recently appointed assistant dean of the University of Pittsburgh School of Medicine, where he took up his duties on October 1.

SOLDIER'S MEDAL AWARDED TO ARMY NURSE

The War Department announced on September 1 the award of the Soldier's Medal to 2d Lieut Margaret M. Decker, Army Nurse Corps, the second woman ever to receive this award, for heroism at Iopar, Calif., on June 19, 1943, when, according to the citation accompanying the award, while swimming in the Colorado River, without regard for her safety she went to the rescue of a soldier and saved him from drowning. Though physically exhausted, Lieutenant Decker administered first aid to the soldier and accompanied him to a station hospital, where he was given medical attention. Lieutenant Decker entered the army on Nov. 19, 1942. She is a graduate of the St. Barnabas Hospital School of Nursing, Newark, N. J., 1938, and is assigned to the 127th Station Hospital, Desert Training Center, Arizona.

PRISONERS OF THE JAPANESE

According to the *Chicago Tribune* of August 12, Lieut Amel L. Palermo, formerly of Chicago, is a prisoner of the Japanese. A card received recently by his mother indicated that he is being held a prisoner in the Philippines in prison No. 1. Lieutenant Palermo graduated from the University of Illinois College of Medicine, Chicago, in 1940 and entered the service on July 5, 1941.

According to the *New Albany (Indiana) Ledger* of September 3, word has been received from Capt Thomas H. Hewlett, formerly of Washington, D. C., that he is safe and well. Captain Hewlett has been held a prisoner of the Japanese since the fall of Corregidor. He graduated from the University of Louisville School of Medicine in 1938 and entered the service in April 1941.

According to the *Stanton (Mich.) Chippea Herald*, word has been received from 1st Lieut Arthur L. Benison, former physician in the Edmore Hospital, Edmore, Mich., who is being held a prisoner of the Japanese. Lieutenant Benison, who graduated from the University of Michigan Medical School, Ann Arbor, in 1937, was a member of a medical unit stationed in the Batran Peninsula.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

QUOTAS OF INTERNS AND RESIDENTS

Since many hospitals have not returned their questionnaires, it is impossible at this time to give every hospital its quota of interns and residents. It was therefore felt advisable to release this memorandum through *THE JOURNAL* so that the state chairmen for the Procurement and Assignment Service and the hospital superintendents would have this additional information concerning the nine-nine-nine program. As soon as the hospitals in each state have been appraised, the state chairmen and the hospital superintendents will be notified of the definite quota which appears as a blank in paragraph two of the following release from the Directing Board:

1 The new intern-resident program based on reduction in the length of internships to nine months and deferment by the Army and Navy of commissioned interns to serve as residents begins Jan. 1, 1944, for nine month periods. This program consists of:

- Nine months internship
- Nine months junior residency
- Nine months senior residency

This program applies to all interns and residents who will have completed nine months of hospital service on or after Jan. 1, 1944. Deferments from active duty which have already been approved by the Army or Navy for residents will be continued to the date authorized.

2 Quota for _____ hospital

_____ internships for nine months period

_____ combined number junior and/or senior residencies for nine months (major portion should be junior residents so that some of them can be retained in senior residencies for nine months period)

Adjustments of this quota may be authorized by the directing board of the Procurement and Assignment Service but will be made only under exceptional circumstances and on the recommendation of the state chairman of the Procurement and Assignment Service.

3 These quotas include all interns and all residents who will serve the institution, including those physically disqualified or otherwise ineligible for military service and those interns who are commissioned officers but who automatically are deferred by the military services for their nine month internships and those residents who are deferred for nine months for either a junior or a senior residency.

4 Failure to limit staffs to these allocated numbers will result in preventing the Procurement and Assignment Service

from requesting the Surgeon General to defer commissioned officers to fill essential residencies in the institution.

5 The greater the number of vacancies filled with applicants who are physically disqualified or otherwise ineligible for military service, the more certain is the maintenance of the house staff, therefore no requests for deferment of commissioned officers should be considered until every effort has been exhausted to fill the vacancies with individuals ineligible for military service.

6 For the deferment of a commissioned officer to fill an essential residency, form number 218 should be completed in triplicate and forwarded to the state chairman of the Procurement and Assignment Service for his approval and submission through the central office to the surgeon general of the service in which the applicant holds a commission. Attention is called to the necessity of the individual recommended for deferment to indicate his desire to accept this appointment by personal signature in the space provided.

7 Hospitals should make contacts and appointments of prospective interns and residents in the usual manner. The Procurement and Assignment Service has no authority to assign interns and residents to hospitals, hence this assignment of an allowable quota is no guaranty that a hospital will be able to procure that number of interns or residents. Hospitals may notify the central office of the Procurement and Assignment Service of vacancies in authorized internships and residencies. This office will arrange for the publication of this information so that individuals who are available and interested may apply for such positions.

8 Certain junior residents who are commissioned officers may be deferred for a third nine months to serve as senior residents within the limitation of authorized quotas. Selection of junior residents and of senior residents may be made from interns and junior residents respectively serving in the same hospital or in other hospitals.

9 Commissioned officers who are to serve as junior or senior residents for nine month periods should be selected at least four months before the termination of their current deferments. Form No. 218 must be submitted promptly for all such individuals in order that deferments may be authorized for the issuance of orders to active duty. Requests for deferment received after orders have been issued cannot be approved.

10 Any questions concerning this announcement or the nine-nine program should be addressed to the state chairman of the Procurement and Assignment Service and not, under any circumstances, to the Office of the Surgeon General.

CIVILIAN DEFENSE

NEED FOR PROTECTIVE SERVICES IN
TIME OF WAR

A memorandum recently issued by the Office of Civilian Defense, Washington, D. C., to regional medical, nursing, engineer, gas and rescue officers states that rumors that civilian defense is no longer necessary have recently been spread by irresponsible persons. These rumors are thoughtless or calculatingly subversive, for they are not supported by Army authorities responsible for our coastal defenses or by the present military situation. Fortunately the success of our armed forces overseas has saved us thus far from experiencing the horrors of enemy bombing to which the cities of our allies are being subjected. In the opinion of the best military authorities our coastal areas and industrial centers will not be free of the danger of enemy attack from the air or of widespread sabotage until the last day of the war.

Civilian defense is also needed as one of the essential measures for safeguarding internal security. This is especially true of the Emergency Medical Service. If we had not created a nationwide organization for civilian defense two years ago, we would be obliged to organize one today for home security. Disasters of all kinds have increased as the result of the tremendous speeding up of our great industries, the overburdening of our railroads and the inexperienced or hundreds of thousands of new war workers. Our police, fire departments, public works and utility services and our hospitals on which we depend for protection are being increasingly depleted of trained personnel. We must therefore strengthen our voluntary protective services throughout the land. Along the Pacific and the Atlantic coasts these services must be especially strong in volunteer personnel and equipment to guard us against the hazards of enemy attack and sabotage until that day when the Army itself advises us that the danger is ended.

MOBILIZATION OF EMERGENCY MEDICAL
SERVICE ON AIR RAID ALERTS

The Office of Civilian Defense, Washington, D. C., issued on September 13 Circular Medical Series No. 33 on the "Mobilization of the Emergency Medical Service on Air Raid Alerts" in which the different colored warning signals are explained as follows:

Yellow Warning Signal—The chief of Emergency Medical Service and his deputies assigned to duty at control centers should receive the yellow warning and proceed immediately to their designated posts. All casualty receiving hospitals should receive the yellow warning which should be relayed immediately to the administrator, the superintendent of nurses and the chief engineer.

Blue Warning Signal—1. Mobile medical teams. (a) Teams composed of resident personnel of hospitals prepare for action by assembling, with equipment, at a designated point in the hospital and stand ready for orders from the control center. (b) Teams composed of persons from the neighborhood of a hospital assemble at the hospital. (c) Teams designated to assemble at casualty stations remote from a hospital report to the casualty station. 2. Stretcher teams. Stretcher teams on call assemble at their posts of duty at hospitals or casualty stations. 3. Ambulance teams (driver and attendant). (a) Teams composed of persons on duty at a hospital or depot at which the ambulance is parked prepare their vehicles and equipment for action. (b) Teams composed of persons residing in the neighborhood of hospitals or ambulance depots assemble at the hospital or depot at which they are on call. 4. Hospital personnel. The following will report to the hospitals to which assigned physicians on shock surgical triage or other emergency teams, anesthetists, nurses and volunteer nurses, on call at the time for emergency duty, hospital protection personnel such as wardens, fire guards, messengers and essential maintenance personnel. In preparing hospitals for action every effort should be made to reduce to a minimum the movement through streets. Hospital administrators and chiefs of staff should therefore determine their minimal requirements and recommend emergency personnel for membership

in the U. S. Citizens Defense Corps or the Civilian Defense Auxiliary Group. The chief of Emergency Medical Service should arrange for the appointment, training and proper identification of such emergency personnel.

Red Warning Signal—Members of the Emergency Medical Service stand by at their posts throughout the red warning period until dispatched to incidents or casualty stations on orders from the control center. The physician in charge of a mobile medical team at a hospital or casualty station may send forward a stretcher team or other personnel to nearby incidents on his own initiative.

Omission of Yellow or First Blue Warning—The sudden or rapid approach of enemy planes may prevent the giving of either the yellow or blue warning, or both. In the event that a red warning is given without preliminary warnings, Emergency Medical Service personnel will immediately take the action normally taken on the yellow and blue warnings.

Blue Warning Signal Following Red—Emergency Medical Service personnel remain at assigned posts or at posts to which they have been dispatched until relieved by the chief of Emergency Medical Service.

All Clear—Emergency Medical Service personnel remain at their posts of duty until relieved by the chief of Emergency Medical Service.

HOSPITAL MEN VOLUNTEERS

The Office of Civilian Defense, Washington, D. C., issued on September 13 Operations Letter 140 to state and local defense councils for the attention of war services boards and volunteer offices, pointing out the acute shortage of manpower in hospitals throughout the country. The Office of Civilian Defense, in cooperation with the American Hospital Association, is working on a plan to promote the use of men volunteers in hospitals where they are needed. At a meeting of the American Hospital Association in Buffalo, September 13-17, the plan as outlined here was presented in order that hospital administrators might be able to hear from their own group what has already been done in some hospitals and how through their local defense councils they can secure help in recruiting men volunteers.

The Health Committee should be asked by the War Services Board to ascertain from hospital administrators the extent of their manpower problem. The Health Committee should appoint a special committee to do this job, and on this committee should be represented the principal hospitals, the Volunteer Office and the Publicity Committee of the Defense Council. If a serious shortage is found the committee should assist the hospitals to determine what assistance hospital men volunteers can give. The committee should then take the following steps:

1. Request the Volunteer Office to obtain men volunteers to work in hospitals.

2. Plan to publicize local needs for men volunteers through the publicity director of the local Defense Council and the Volunteer Office using all appropriate mediums such as newspapers, the radio and speakers.

3. Plan with hospital administrators, the Volunteer Office and the Training Committee of the Defense Council for organizing hospital staffs for the proper use of volunteers including provision for their training and supervision.

4. Arrange with the executive of the Citizens Service Corps for special induction ceremonies and awarding of insignia to the men hospital volunteers.

The Volunteer Office should be responsible for securing the hospital men volunteers. The following points will guide the Volunteer Office in fulfilling this responsibility:

1. The files should furnish the first source of volunteers. If there is not a sufficient number of suitable men required recruiting should be undertaken at once.

2. The general public can be reached most effectively through the press and the radio. Stories should indicate clearly at kind of men volunteers are wanted, how many are needed, where they will work, and when and where interested men can be interviewed.

3. Medical schools and college provide another source. Speakers should be sent to explain the need to secure men

and convenient arrangements should be made for interviewing interested men.

4 Organized men's groups such as labor organizations, church groups, ministers organizations, fraternal organizations and men's civic groups, are a potential source. Organizations of the clergy are an especially good source. Speakers should be made available to these men's organizations, and convenient arrangements should be made for interviews with interested applicants.

5 Selection from among men volunteers either enrolled or especially recruited should be carefully made on the basis of specifications of the various hospitals.

6 Referrals should be made directly to the hospitals as long as the hospitals' need for men volunteers continues to be unfilled.

7 Follow-up on referrals should be made to determine whether the hospitals are satisfied, and replacements should be made whenever necessary.

MISCELLANEOUS

U S CADET NURSE CORPS PROGRAM

According to the Division of Nurse Education, U S Public Health Service, Washington, D C, expansion of housing and educational facilities will be necessary to train nursing schools if the required number of student nurses are to be enrolled in the U S Cadet Nurse Corps. Institutions which cannot finance the entire cost of such additions are eligible to apply for assistance under the Latham act if they are participating in the Cadet Nurse Corps program. New construction must be avoided wherever possible by leasing or purchasing an existing building which can be suitably altered. Institutions applying for financial aid under the Latham act should make a preliminary request to the regional office of the Federal Works Agency having jurisdiction in the state. Institutions which do not require financial assistance should make application for priorities assistance directly to the War Production Board, Washington, D C, on form WPB 617. WPB 28141 will accompany WPB 617. In the "hospital section" of WPB 28141 only questions pertinent to the applicant hospital need be answered. In the "nurses home" section, all questions must be answered.

WARTIME GRADUATE MEDICAL MEETINGS

On October 14 a conference under the auspices of the Wartime Graduate Medical Meetings will be held at the Army and Navy General Hospital at Hot Springs, Ark., with Lieut. Col. Irving S. Wright, M C, as chairman. The schedule will include papers entitled "Studies on the Mechanism of Recovery from Pneumococcal Pneumonia" by Dr. Barry Wood and "Allergy as It Is Related to Bronchial Asthma," with case presentations by Dr. Harry Alexander, and a round table in which Lieutenant Colonel Wright, Dr. Wood, Dr. Alexander and Major Dudley C. Ashton, M C, will take part.

On October 7 a conference was held at the same hospital on "Malignant Diseases in Military Age."

Other recent programs under the auspices of the Wartime Graduate Medical Meetings have been held at the Station Hospital, Fort Sill, Oklahoma, and Will Rogers Field, Oklahoma City.

RELIEF WINGS INCORPORATED

Relief Wings, Inc., with headquarters at 80 East 42d Street, New York City, is a nonprofit organization for aerial mercy aids to civilians. The air ambulance service which this institution conducts is offered to charity patients at a cost of 5 cents per mile. For those patients who are able to pay the full operating cost of the airplane a charge of 14 cents per mile is made to cover all necessary costs. Flight surgeons and flight nurses on registers throughout the United States who have been receiving aeromedical training on the care of the airborne patient are available.

Dr. Harry V. Spalding is chairman of the organization's Aero Medical Research Committee. Miss Ruth Nichols, well known aviatrix, is the executive secretary. Among the sponsors, officers, sectional leaders and advisory committees of Relief Wings, Inc., are nationally known citizens, aviators and scientists.

This organization is largely maintained by the donations which it receives, and contributions may be sent to Relief Wings, Inc., at 342 Madison Avenue, New York City.

PUBLIC HEALTH UNDER HITLER

According to NDZ of July 12 the increased employment of women and the burdens thus placed on large families have made it necessary to extend the day nursery scheme and give more help to mothers of large families. The NSV needs assistance for these tasks. As far as it is not possible to meet this demand through normal channels, young girls will be called up for this purpose. This kind of war work is specially suited to the natural inclinations and interests of girls, as it consists exclusively of feminine tasks. It will not only enrich the knowledge and increase the ability of the girls but also in many cases inspire them in their choice of a vocation.

The Reich youth leader, the general trustee for the direction of labor and the minister of education have issued the directives for this work in a joint decree. They say that, where in special cases the requirements cannot otherwise be met by the labor offices, girls of the seventh form of *oberschulen* can be made available. The present seventh form will be employed on this work until August 31. They will take their holidays from September 1 to 20 and will enter the eighth form on September 21. They will be relieved by the girls of the new seventh form. These girls will be employed from Sept. 1, 1943 until Feb. 26, 1944, at the latest.

The Social Welfare Office of the Reich Youth Directorate has been entrusted with the organization of this scheme. The girls may work, first, as assistants in day nurseries, in small harvest, agricultural and auxiliary kindergartens, and, secondly, in NSV recuperation institutions for juveniles and in connection with the Extended Child Evacuation Scheme. Where the need for assistants is fully covered, the girls may be employed to reinforce the NSV domestic help scheme locally or within the *kreis*. They must, however, be able to sleep at home. Before work of this kind is started there will always be parents' meetings at the schools, at which further details of the work will be announced. The cost of accommodation, food, insurance, fares and pocket money of 15 reichsmarks per month will be borne by the NSV.

Nachrichten für den Aussenhandel of May 17 states that, owing to shortage of fish in Bulgaria, food preserving factories have been temporarily prohibited to preserve fish. This measure was deemed necessary in order to provide the population with as much fresh fish as possible. Despite the efforts of the authorities, insufficient fish has been landed lately, especially on the Black Sea coast, where the industry has been greatly handicapped by war conditions. Fishing tackle has become scarce and is difficult to replace in wartime. In the opinion of the fishermen the relatively low prices are also partly responsible for the present shortage. An appeal for higher prices was refused by the authorities.

L'Action française of July 24 complains that children under 3 are not entitled to certain rationed food such as calf brain, liver, eggs and ham, which they need more than certain other categories. The birth rate is higher than five years ago, but too many infants die as a result of malnutrition. Since mothers have been encouraged to have more children, it is essential to feed the children properly.

The *Deutsche Zeitung in den Niederlanden* of July 14 states that 99 per cent of the doctors who wrote the second letter to Seyss-Inquart have apologized to him. They are said to have declared that many of the signatures were forced.

ORGANIZATION SECTION

MEDICAL ECONOMIC ABSTRACTS

HOW MANY PHYSICIANS ARE NEEDED

The United States Public Health Service has made a questionnaire study on medical conditions in the District of Columbia, Baltimore City, certain Maryland counties and Georgia. The average weekly patient load is shown in the following table.

Place of Practice	Averages			
	Office	Hospital	Home of Patient	Total
District of Columbia	86	8	21	115
Maryland				
Baltimore	82	6	31	119
Exclusive of Baltimore	66	7	29	102
Total	89	7	50	126
Georgia				
Urban	78	11	23	112
Rural	70	6	26	102
Total	79	7	25	111

The averages, however, are somewhat deceptive, as they vary greatly according to age. Physicians under 45, especially those from 35 to 44 inclusive, care for two to three times as many as those above 64 years of age. The number of patients that can be seen naturally varies with the proportion of office and home visits. With considerable variation the average office hours in Baltimore for physicians are between four and five, while in the counties outside they are about an hour longer. The same difference exists between urban and rural counties in Georgia.

An effort was made to determine the possible optimum patient load. Sixty per cent of urban general practitioners declared that they could increase the present load. The remainder declared that they are caring for as many patients at present as they could manage. Only forty-nine per cent of rural physicians thought that they could care for more patients. This would mean an increase from 112 and 111 patients for urban and rural general practitioners respectively to 135 and 128 patients. From these facts some general conclusions are drawn. It is calculated that the number of persons per physician cannot be increased beyond 1,200 to 1,500 in Maryland and 2,000 to 2,400 in Georgia. This conclusion, however, is affected by the fact that it is measured in both need for medical services and by the economic demand, and it is not certain that this would not be changed if economic conditions improve in Georgia, for example. The ratio of physicians to population constitutes nothing more than index of the maximum amount of services that can be provided, but whether or not the physicians' potential services are fully utilized will depend not on their number but on the effective demand for services.

1. Cicco, Antonio and Altman, Isidore. The Patient Load of Physicians in Private Practice. *Pub. Health Rep.* 58: 1529 (Sept.) 1943.

AN OPTIMISTIC OUTLOOK

Recent bulletins of the Metropolitan Life Insurance Company bring a combined message of remarkable improvement in vital conditions in the United States. In the first place we learn that, "despite the hardships of war, American wage earners and their families are living on the average longer than ever before."

Not only are we living longer but there is a promise that there will be more of us since "a steady rise in the American birth rate since 1933 will have paid, by the end of this year, a dividend of 2,000,000 additional babies for the ten year period."

The added number of births is also accompanied by a striking decline in the maternal death rate, so that childbearing in this country is now safer than ever before, since "only about one third as many American mothers currently lose their lives in childbirth as compared with ten years ago. About two maternal deaths per thousand live births now take place in the United States, while prior to 1934 the rate was between six and seven per thousand."

Meanwhile, although there has been a recent outbreak of cerebrospinal meningitis which was the most extensive in the country's history, fortunately in 1943 we have a powerful weapon against this disease. The great majority of cases are now cured by the sulfa drugs which have revolutionized the treatment of the disease. In the general population, prior to 1939 the proportion of deaths to cases was more than 40 per cent.

Preliminary data for 1942 for this country give a fatality rate only slightly more than 20 per cent. Where facilities for diagnosis and early treatment are better than average, fatality rates of 10 per cent or less are experienced. Indeed, in our army camps the rate has been only 3.5 per cent, as compared with 34 per cent in the first world war."

NEW HAMPSHIRE PREPAYMENT PLAN

The house of delegates of the New Hampshire Medical Society meeting at Concord, N. H. on September 12, accepted a report of a committee on medical economics giving a detailed outline of a prepayment nonprofit organization. This plan will include the rural areas and according to a report in the *Union* (Manchester, N. H.), will provide for premiums that "will appeal to the lower and middle, as well as the higher income brackets. The organization will be known as the Blue Shield and will be administered through the New Hampshire Blue Cross Hospitalization Plan. The house of delegates authorized the medical economics committee to work out details for the establishment of a corporation.

The house of delegates also adopted a resolution condemning the Wagner-Murray-Dingell bill and stated that in its opinion the need for improvement in the distribution of medical care can best be met by the extension of existing voluntary plans for medical and hospital care.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Change in Status—H. R. 159 has passed the Senate appropriating \$18,600,000 for grants to states including Alaska, Hawaii, Puerto Rico and the District of Columbia to provide in addition to similar services otherwise available medical nursing and hospital maternity and infant care for wives and infants of enlisted men of the fourth, fifth, sixth and seventh grades in the armed forces of the United States under allotments by the Secretary of Labor and plans developed and

administered by state health agencies and approved by the chief of the Children's Bureau. An additional appropriation of \$20,000 was also made available for salaries and expenses of the Children's Bureau in carrying out the program.

The federal money that is made available for grants to states may be used for payments of contributions made prior to Oct. 1, 1943 for similar services to the wives and infants of enlisted men of the first, second and third grades of armed forces.

Medical News

(PHYSICIANS WILL CONFIRM A FAVOR BY SIGNING FOR THIS DECLARATION OF VIEWS OF MORAL OR ETHICAL PRINCIPLES SUCH AS RELATE TO SOCIETY, ACTIVE LIFE IN HOSPITALS, EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Alumni Research Foundation Created—The Alumni Research Foundation of the College of Medical Evangelists, Los Angeles, has been created by recent action of the board of directors of the Alumni Association and the board of trustees of the College of Medical Evangelists. The foundation is incorporated under the laws of California. While the primary purpose is to stimulate research, it may also accept gifts, grants, bequests and other forms of property to be used for charitable or educational purposes to aid the College of Medical Evangelists or advance medical science. At the first meeting of the board August 8 the by-laws were ratified and Dr. Newton G. Fyans, dean of the medical college, was elected president. The foundation consists of twelve to fifteen trustees.

COLORADO

Physician's Conviction Reversed by Supreme Court—Conviction of Dr. Philip L. Cobianchi, Denver, on the charge of performing an illegal operation, was reversed on August 3 by the Colorado Supreme Court, newspapers reported. It was stated that the evidence submitted "was insufficient to support the charge." Statements to the press indicated that the physician was convicted in 1942 on a charge of performing an illegal operation in 1941, the patient dying a few months later of peritonitis. The supreme court held that the pregnancy of the woman was not proved beyond doubt and testimony was that she had undergone an operation for appendicitis subsequent to the purported illegal operation. The newspaper reports stated that Dr. Cobianchi was sentenced to ten to twelve years for second degree murder. Newspaper accounts implied that the state will file a motion with the supreme court for a rehearing, the intimation being that the physician would be held on other charges still on file in the district court.

FLORIDA

Appointments in State Health Department—The appointment of Dr. Elmer J. Teagarden, Orlando, and Dr. Estella Lucille Johnson Marsh, Tallahassee, as directors of the state board of health's bureau of tuberculosis and bureau of maternal and child health, respectively, were reported on September 3. Dr. Teagarden has been serving as superintendent of the Morgan County Tuberculosis Sanatorium, Flint (Decatur P. O.), Ala., and succeeds Dr. Lynne E. Baker, Jacksonville, who resigned to enter private practice in Dayton, Ohio, last July. Dr. Marsh has been serving as chief physician at the Florida State College for Women, Tallahassee. Since the resignation of Dr. Robert C. Hood, Jacksonville, to enter private practice in Arlington, Va., the latter part of 1942, the bureau of maternal and child health has been in charge of Dr. Erwin F. Hoffman, director of the bureau of epidemiology.

ILLINOIS

Springfield Hospital Dedicated—The dedication of the new Memorial Hospital of Springfield took place September 26. The new building occupies a four block site and was erected at a cost of \$1,800,000. It has 285 beds and 50 bassinets. Of brick construction with concrete trimming, the building is composed of a central tower ten stories high and three wings seven stories high. At the dedication exercises the speakers included Lieut. Col. Charles W. Mayo, M. C., A. U. S., Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, on "What a Standardized Hospital Means to a Community", Dr. Malcolm T. MacEachern, Chicago, associate director of the American College of Surgeons, and Dr. Warren P. Morrill representing George Bugbee, executive secretary, American Hospital Association, Chicago. The Illinois State Journal and Register devoted a special section, September 26, to a review of the hospital's development and to features emphasizing the modern installations and accommodations. The section also carried pages of congratulatory messages from local physicians and commercial and other firms.

Chicago

Dr. Wynkoop Refused Request for Freedom—Dr. Alice L. Wynkoop, who is serving the tenth year of her sentence for conviction in the murder of her daughter-in-law, was denied a writ of habeas corpus by Federal Judge John P. Barnes, September 11, newspapers report. Dr. Wynkoop is serving a twenty-five year sentence in the women's prison at Dwight, Ill.

Dr. Elvehjem Lectures on Vitamin B Complex—Conrad A. Elvehjem, Ph.D., professor of biochemistry, University of Wisconsin, Madison, will address the annual joint meeting of the Institute of Medicine of Chicago and the Chicago Society of Internal Medicine at the Palmer House on October 25. His subject will be "The Nutritional Significance of the Newer Members of the Vitamin B Complex."

Dr. Bachmeyer Receives Hospital Award—Dr. Arthur C. Bachmeyer, director and associate dean of the biology division of the University of Chicago Clinics, was presented with the American Hospital Association's Award for meritorious service to the hospital field during a meeting of the association on September 13. According to the inscription on the medal constituting the award, Dr. Bachmeyer was recognized as a "distinguished administrator and educator whose achievements have greatly advanced standards of treatment for patients and educational opportunities of lasting benefit to his fellow citizens."

KENTUCKY

Pediatric Conferences—On October 22 Drs. Philip F. Barbour, Louisville, and J. Garland Cherrill, consultant in pediatrics and consultant in surgery for children, respectively, for the state department of health, will conduct a pediatric conference in Corbin with the Whitley County Medical Society and the county health department. The program will include lectures and a clinic. The Muhlenberg County Medical Society will present a meeting on October 24 in Greenville, including a pediatric and obstetric clinic. A pediatric conference will be offered in Pineville, October 29, with Dr. Thomas M. Mark, Lexington, and Dr. Barbour in charge. Dr. Stanley S. Parks, Lexington, will be available as a consultant on obstetric patients. On November 12 a pediatric clinic will be conducted by Dr. Robert B. Warfield, Lexington, and Dr. Barbour in Paintsville, with Dr. A. J. Whitehouse, Lexington, as consultant in obstetric care. These various programs are being held throughout the state under the sponsorship of the county medical societies and the local health departments and under the general supervision of the state medical association and the state department of health.

MISSOURI

Health Board Resigns in Protest—Resignation of all members of the health board of Cape Girardeau in protest against failure of the city to follow its recommendations for more strict scrutiny of milk distribution and adoption of rules regulating health conditions in restaurants was accepted by the city council on August 2, newspapers report. A complete new board was appointed. Retiring board members included Drs. Carl A. W. Zimmermann, chairman, William F. Oechler, John H. Cochran and Raymond A. Ritter. Members of the new board are Drs. Gustav B. Schulz, Alexander E. Dalton, Hugh L. Ashley and Amos M. Murphy.

Report of State Cancer Hospital—A total of 3,574 patients have been examined in the Ellis Fischel State Cancer Hospital in Columbia from the time it opened in May 1940 through Feb. 28, 1943. There have been 13,225 clinic visits. These patients came from practically every county in the state with the exception of the St. Louis and Kansas City districts. The 931 physicians who sent patients to the hospital make up 48.6 per cent of all the physicians in the state, exclusive of Kansas City and St. Louis. One physician sent 49 patients. The average hospital stay per patient for 1942 was 18.5 days. The cost per patient day was \$6.30. About 40 per cent of the proved carcinoma cases and 25 per cent of the surgical pathology cases were made up of skin lesions. Carcinoma of the rectum was a fairly common lesion, and of 81 consecutive cases, 57, or 70 per cent, were resectable. According to a report published in the state medical journal by Dr. Lauren V. Acherman, medical director and pathologist of the hospital, 150 cases of carcinoma of the breast are seen yearly, as 150 radical mastectomies are being done. Thus far there have been no operative deaths. The distribution of carcinoma at the cancer hospital does not conform with accepted statistical studies, it was stated. To consider how many patients have true carcinoma, a thousand consecutive cases were analyzed and the most important disease was present in only 52 per cent. Forty-three

cent were proved definitely not to have carcinoma and 5 per cent could not be classified. Of the nonmalignant lesions 341 were located in the uterus, skin, breast, stomach, rectum, penis and sigmoid. According to the state law all patients admitted to the hospital must be indigent, as certified by the patient's local county court, and a diagnosis of carcinoma or precancerous condition must be made by the referring physician from that county. All patients admitted to the hospital with malignant disease are treated from a curative or palliative approach. Patients with advanced disease which cannot be benefited by treatment are not admitted.

NEBRASKA

Mid-West Clinical Society—The Omaha Mid-West Clinical Society will hold its eleventh annual assembly at the Hotel Paxton Omaha, October 25-29. Among the out of state speakers will be

Dr. Harold G. Wolff, New York: Headache Mechanisms
Dr. Jennings C. Litzberg, Minneapolis: Management of Occiput Posterior
Dr. Frank R. Ober, Boston: Infantile Paralysis
Dr. Raymond W. McNealy, Chicago: Advances in Blood Vessel Surgery
Dr. Sam M. Jordan, Boston: Functional Disorders and the War
Dr. Luther Emmett Holt, Jr., Baltimore: Unusual Cerebral Disorders in Childhood
Dr. Sanford R. Gifford, Chicago: Treatment of Some Corneal Diseases
Dr. Robert L. Sander, Memphis, Tenn.: Complications of Duodenal Ulcer
Dr. Tom D. Spies, Birmingham: Detailed Methods of Diagnosis and Therapy in Acute Nutritive Failure
Col. Rexford L. Drivley, M. R. C.: The Work of the Rehabilitation Centers in England (tentative)
Dr. Cyrus E. Burford, St. Louis: Present Day Management of Carcinoma of the Prostate
Major General Norman T. Kirk, surgeon general of the U. S. Army: Amputations (tentative)

There will be symposiums on peripheral vascular diseases, pneumonia and shock and special lecture courses. Thursday evening has been designated "Omaha-Douglas County Medical Society Night" and speakers will include Dr. Eben I. Carey, Milwaukee, on "Medical Education of Today and Its Effect on the Future of Medicine." The session will conclude Friday morning with a panel discussion on "War Medicine and Surgery" with Capt. Henry L. Dollard (MC), U. S. Navy, acting as chairman. Other speakers will be

Capt. Emil J. Stelter (MC), U. S. Navy: Aviation Medicine and Research
Commander John F. Luten (MC), U. S. Navy: Treatment of War Casualties Including Shock, Placenta and Sulfonamides
Lieut. Commander Franklin C. Southworth Jr. (MC), U. S. Naval Reserve: Neuropsychiatric Screening of Recruits at a Naval Training Station
Lieut. Commander Charles W. McLaughlin Jr. (MC), U. S. Naval Reserve: Corrective Surgery
Lieut. Commander Joseph M. Picciochi (MC), U. S. Navy: 2,000 Photographs of the Cheeks of Naval Recruits

NEW HAMPSHIRE

Dr. Mary Atchison Named Acting State Health Officer—Dr. Mary M. Atchison, formerly director of the divisions of maternal and child health and crippled children's services, New Hampshire State Board of Health, Concord, and recently acting deputy secretary of the state board, has been appointed acting state health officer. Dr. Atchison fills the vacancy that occurred when Dr. Alfred L. Frechette was granted a leave of absence as secretary of the board to engage in war rehabilitation work under the auspices of the U. S. Public Health Service (THE JOURNAL, July 17, p. 821).

The Mayo Lectures—Capt. Winchell M. Craig (MC), U. S. Naval Reserve, chief surgeon, Naval Hospital, Naval Medical Center, Bethesda, Md., will deliver the W. J. and C. H. Mayo Memorial Lecture at Dartmouth Medical School, Hanover, November 5. The title of his address will be "Warriors Against Disease." The lecture was established in 1942 by Dr. and Mrs. Waltman Walters, Rochester, Minn., as a stimulating factor in interesting men in medicine and surgery and, particularly, to call attention to the accomplishments of Drs. W. J. and C. H. Mayo in these fields.

NEW JERSEY

Schireson's License Restored—The New Jersey state court of pardons and appeals set aside on September 24 the action of the state board of medical examiners in revoking the license of Dr. Henry J. Schireson, Merchantville, plastic surgeon, according to the New York Times. The errors court in an opinion written by Chief Justice Thomas J. Brogan held that although Schireson at the time his license was revoked April 15, 1942, was serving a federal penitentiary sentence for perjury, false swearing and concealing assets in federal bankruptcy proceedings, the physician had not been convicted of a crime.

The report stated Schireson was once involved in a notorious damage suit in which he was ordered to pay the complainant \$40,000. Since then his licenses to practice medicine in various states have been revoked.

NEW YORK

New Building at Lederle—A five story and basement reinforced concrete and brick factory and laboratory building has been started at the Lederle Laboratories Inc., Pearl River. The expansion is in accordance with recently approved priorities from the War Production Board to meet the required need of penicillin.

Personal—Dr. William T. Shanahan has retired as medical superintendent of the Craig Colony, Sonoma, effective October 1. He plans to live in Eggertsville. Dr. Shanahan has been medical superintendent for thirty-two of the forty-seven years with which he has been connected with Craig Colony, an institution for the epileptic.

New York City

Tuberculosis Package Library—The Queensboro Tuberculosis and Health Association launched a library health package service recently to supply, free of charge, new books, pamphlets and research studies on tuberculosis to libraries throughout the borough.

Louis Livingston Seaman Fund—The New York Academy of Medicine announced that the Louis Livingston Seaman Fund of \$1,000 is now available. Applications will be received either from institutions or from individuals up to November 1. The fund will be expended only in grants in aid for investigation or scholarships for research in bacteriology or sanitary science and may be made for securing or technical help, aid in publishing original work and the purchase of necessary books or apparatus. The fund was made possible by the terms of the will of the late Dr. Louis Livingston Seaman. Additional information may be obtained from Dr. Wilson G. Smillie, chairman of the fund, 1300 York Avenue.

Grant for Undergraduate Psychiatric Education—The Commonwealth Fund has awarded a six year grant to the Long Island College of Medicine, Brooklyn, for the development of undergraduate psychiatric education, beginning with the sum of \$20,450 toward the current budget. The aims of the projected program are to train the medical student to understand and recognize the personal and environmental factors that often contribute to ill health both physical and mental, the impact of somatic illness on personality, and the diagnosis and treatment of psychologic problems long before these grow into fully developed psychiatric disorders as one of the responsibilities of physicians in the mental hygiene area of public health and hygiene.

Opinion Reverses Revocation of Compensation License—In a decision handed down on September 8 Supreme Court Justice Carroll G. Walter voided an action of the New York State Industrial Commission in revoking the authority of Dr. Leo S. Sacharoff to treat workmen's compensation cases. Dr. Sacharoff lost his license to care for this work on August 11 by order of the state labor department because of fee splitting and other misconduct (THE JOURNAL, September 4, p. 46). The physician's right to treat such cases was rescinded as a result of the Moreland commission's investigation into the administration of the workmen's compensation act. In annulling the revocation action Justice Walter held that the commissioner had no legal right to hold a hearing and that the charges of professional misconduct first should have been heard by the county medical society having jurisdiction according to the New York Times. In the event that the medical body sustained the charges Justice Walter pointed out in his decision, the industrial commissioner might then act to revoke the physician's right to administer to compensation cases.

NORTH CAROLINA

Dr. Ferguson Named Professor of Physiology—Dr. John H. Ferguson, assistant professor of pharmacology, University of Michigan Medical School, Ann Arbor, has been appointed professor and head of the department of physiology at the University of North Carolina School of Medicine, Chapel Hill. Dr. Ferguson graduated at Harvard Medical School, Boston, in 1928.

New Building for Health Unit—A new two story building has been erected in Wilmington for the consolidated board of health of New Hanover County and the city of Wilmington. Most of the lower floor is given to the clinical examination and treatment rooms and offices of the various departments and the fluoroscope room. The second floor is devoted to

administrative facilities. The general public health laboratory and the venereal disease laboratory will remain in the court house. The unit was constructed by the Federal Works Administration which leased the lot and constructed the building at a cost of about \$30,000. Ultimately the lease will be terminated and the lot and building will be turned over to the county.

OHIO

Industrial Funds Distributed Reach New High—The state industrial commission disbursed \$1,213,069.09 for medical services to injured Ohio workers during 1942, according to a recent report. The figure which established a new record for this expenditure, includes a relatively small amount for essential dental services. Other expenditures during the year included \$1,760,898.69 for hospital care and nursing, \$133,104.11 for funeral expenses and \$84,611.31 for court costs, a total of \$6,223,733.53. These amounts include payments covering injuries to private and public employees as well as similar costs on occupational disease claims and are in addition to death awards and compensation to injured employees. Comparative figures for 1941 were \$3,322,792.06 for medical services, \$1,258,095.36 for hospital care and nursing, \$122,290.05 for funeral expenses and \$73,998.89 for court costs, a total of \$4,777,177.26. The number of claims filed during 1942 was 320,793, also a record in the thirty-one year history of the Workmen's Compensation Fund. There were 286,010 claims filed in 1941, the previous peak year. The total for 1932 was 130,099. "Medical only" claims involving payment for physicians' services but no compensation to the claimant for loss of time numbered 256,600 in 1942 or 80 per cent of all claims filed compared with 79.5 per cent in 1941. Average expense of "medical only" claims decreased from \$8.03 in 1941 to \$7.69 in 1942.

OKLAHOMA

Thirteenth Annual Clinic Society Conference—The Oklahoma City Clinical Society will hold its thirteenth annual conference at the Biltmore Hotel, Oklahoma City, October 18-21. The guest speakers will be:

- Dr. Louis F. Phelan, Boston: Evolution, Indications and Contra-indications of Calcium Section.
- Dr. Abraham H. Aaron, Buffalo: The Management of Peptic Ulcer from the Standpoint of the Active Practitioner.
- Dr. Charles T. Way, Cleveland: Clinical Problems Involving Water, Protein and Solute Replacement.
- Dr. Grayson I. Carroll, St. Louis: The Clinical Management of Pyuria.
- Dr. Robert D. Schrock, Omaha: Fractures at the Knee Joint.
- Dr. Vilray P. Blair, St. Louis: The Importance of Proper Early Treatment of Face Injuries.
- Dr. John A. Foomay, Cleveland: Chemotherapy in Acute Infectious and Contagious Diseases.
- Dr. Leroy A. Calkins, Kansas City, Mo.: I Haven't Been the Same Since Mary Was Born (a diagnostic problem).
- Dr. Theodore I. Dimitry, New Orleans: The Modern Trend in the Treatment of Eye Diseases.
- Dr. Thomas G. Orr, Kansas City, Mo.: Analysis of Gallbladder Cases.
- Dr. George B. Eusterman, Rochester, Minn.: "When Johnnie Comes Marching Home" (diagnostic and therapeutic problems facing the practitioner and how to meet them).
- Dr. Harry E. Mock, Chicago: Skull Fractures and Brain Injuries (a review of the management of 7,031 cases treated throughout the United States).
- Dr. Louis A. Bue, Rochester, Minn.: Lesion of the Terminal Portion of the Colon.
- Col. Franklin G. Ebaugh, M. C., A. U. S.: Basic Neuropsychiatric Induction Examination Problem (How the General Medical Profession Can Help).
- Dr. W. Likely Simpson, Memphis, Tenn.: Diagnosis and Treatment of Sinusitis.
- Dr. Clinton W. Irwin, St. Louis: Contact Dermatitis with Particular Reference to Occupational Dermatitis.

The program will also include round table luncheons and banquets.

OREGON

Life Members of State Society—At a meeting of the council of the Oregon State Medical Society, August 14, life membership was voted to Drs. Charles T. Sweeney, Medford, George Norman Pease, Portland, William T. Johnson, Corvallis, and the late Wilson Johnston, Portland.

Dr. Weeks Observes Ninetieth Anniversary—Dr. John E. Weeks, professor emeritus of ophthalmology, New York University College of Medicine, New York, celebrated his ninetyeth birthday recently. Dr. Weeks was for many years professor of ophthalmology at University and Bellevue Hospital Medical College, New York, becoming emeritus professor in 1920. He was chairman of the Section on Ophthalmology of the American Medical Association in 1902.

SOUTH CAROLINA

Dr. Routh Resigns from State Board—Dr. Foster M. Routh, Columbia, for many years a member of the executive committee of the state board of health and chairman in 1935, resigned as a member of the board on August 18 because of

ill health. Dr. Robert B. Durham, Columbia, has been named to succeed Dr. Routh, who will continue his work as resident physician at the University of South Carolina, Columbia. Dr. Routh graduated at the Medical College of the State of South Carolina, Charleston, in 1910.

TENNESSEE

New State Health Officer—Dr. Robert H. Hutcheson, Nashville, assistant commissioner and one time superintendent of the Williamson County Health Unit, has been appointed state commissioner of public health. He succeeds Dr. Wilson C. Williams, Nashville, who accepted a commission as lieutenant colonel in the Medical Corps of the Army and who has been ordered to active duty. Dr. Hutcheson graduated at the University of Tennessee College of Medicine, Memphis, in 1930.

UTAH

State Medical Election—Dr. Ezekiel R. Dumke, Ogden, was named president-elect of the Utah State Medical Association at its annual session in Salt Lake City and Dr. James P. Kerby, Salt Lake City, was inducted into the presidency. Other officers include Drs. Wilford Woolf, Provo, LaVile H. Merrill, Spring Canyon, and Mildred N. Nelson, Salt Lake City, vice presidents, Dr. David G. Edmunds, Salt Lake City, secretary, and Dr. Edward S. Pomeroy, Salt Lake City, treasurer. The next annual session will be held in Salt Lake City some time in August 1944.

WISCONSIN

Physicians Honored—The Waukesha County Medical Society held a banquet recently at the Draper Hall, Oconomowoc, to honor Drs. Michael R. Wilkinson, Oconomowoc, Byron M. Caples, Waukesha, and Francis J. Donnelly, North Lake, in recognition of their completion of fifty years in the practice of medicine, each was awarded an honorary life membership in the county society.

Will Provides for Hospital—The estate of the late Dr. William H. Finney will eventually be available for the erection and maintenance of the William Finney Memorial Hospital in Clintonville under the provisions of the physician's will filed on July 30. The estate is estimated to be about \$400,000 and will be divided among the beneficiaries during their lifetime. On their deaths one half is to go to the city of Clintonville to build and equip a modern hospital to bear his name.

GENERAL

Examination in Otolaryngology—The American Board of Otolaryngology announces that it will conduct an examination in Los Angeles, February 2-5, provided fifty applicants are accepted.

New Executive Director of the Russian War Relief—Fred Myers, public relations director of Russian War Relief, New York, since its inception in 1941, has been appointed executive director to succeed Arch Mandel, who resigned to join Community Chest and Councils, Inc.

Meeting of Industrial Hygiene Foundation—The eighth annual meeting of the Industrial Hygiene Foundation will be held at the Mellon Institute, Pittsburgh, November 10-11. At a meeting of the board of trustees on August 25 it was decided to hold the meeting as a help in maintaining healthful conditions in war plants, which in turn helps maintain manpower.

Casselberry Award—The American Laryngological Association announced that a sum of money has accrued from the Casselberry Fund to insure a prize being offered in 1944 to original investigation in the art and science of laryngology or rhinology. Theses must reach the secretary, Dr. Arthur W. Proetz, 1010 Beaumont Building, St. Louis 8, before March 1, 1944.

Examinations for Medical Technologists—The Registry of Medical Technologists of the American Society of Clinical Pathologists announces that examinations of applicant technologists will be conducted in various parts of the United States and Canada on October 29. Additional information may be obtained from Dr. Lall G. Montgomery, chairman of the Board of Registry of Medical Technologists, Ball Memorial Hospital, Muncie, Ind.

Society News—The National Association for Nursery Education will hold its tenth biennial meeting at the Hotel Statler in Boston, October 22-25. There will be a conference on "The Community Serves the Child in War and Peace" and a session on "The World Picture and the Implications for Education." Other sessions will consist of study groups, etc.

discuss child development problems based on actual case histories of various communities. Dora-Louise Cockrell, state social security commission, Jefferson City, Mo. is the secretary of the National Association for Nursery Education.

Brazilian Physician Lectures on Tropical Medicine—At the invitation of the Pan American Sanitary Bureau Dr. Olympio da Fonseca Jr., medical director for Brazil for E. R. Squibb and Sons Inter-American Corporation has arrived in the United States for an extensive lecture tour before the faculties and students of medical schools throughout the country, discussing tropical medicine with special emphasis on malaria, African sleeping sickness, amebic dysentery and ringworm infection. Dr. da Fonseca is a professor at the National School of Medicine of the University of Brazil and is connected with the Medical Center of Ceara and the department of health of that state.

Special Society Elections—Dr. Fuller Albright, Boston, is president of the American Society for Clinical Investigation for 1943-1944, and Dr. Wesley W. Spink, Minneapolis is secretary. Dr. H. Marshall Taylor, Jacksonville, Fla., is president of the American Laryngological, Rhinological and Otolological Society. The society did not have an annual meeting this year, and the council promoted Dr. Taylor from president-elect to president. He succeeds Dr. James G. Duver, New York, who resigned as president. Vice presidents appointed for the ensuing year are Dr. Westley M. Hunt, New York, William C. Warren Jr., Atlanta, Ga., Fred W. Dixon, Cleveland, and Simon Jesberg, Los Angeles.

Profession-Industry Follow-Up Conference—The second Profession-Industry Follow-Up on the National Conference on Planning for War and Postwar Medical Services was held at the Waldorf-Astoria, New York, October 4 under the auspices of the National Physicians Committee for the Extension of Medical Service. Among the speakers on the program were Dr. Roger I. Lee, Boston, on "Medicine's Position and Policy," Raymond Moley, Ph.D., New York, "The Cult of the Uncommon Man," and Dr. Morris Fishbein, Chicago, Editor of *THE JOURNAL 'Medical Planning and Progress'*. Dr. Edward H. Carv, Dallas, Texas, was chairman at the meeting, at which the financial report and reports covering the educational efforts and the profession-industry cooperation were reviewed.

Remington Award Goes to Dr. Fischelis—Robert P. Fischelis, Ph.M., Trenton, N. J., chairman of the council of the American Pharmaceutical Association, has been awarded the 1943 Remington Medal, conferred by the New York Branch of the American Pharmaceutical Association. Dr. Fischelis, who is secretary and chief chemist of the Board of Pharmacy of the State of New Jersey and chief of the chemicals, drugs and health supplies branch of the Office of Civilian Requirements of the War Production Board, was presented with the medal for his many contributions to the advancement of pharmacy, including his literary, scientific and organizational activities. He has recently been reappointed as the pharmacist member of the state board of health of New Jersey for a term of four years. The Remington Medal is awarded annually to the man or woman who has done most for American pharmacy during the preceding year or during a longer period of outstanding activity and of fruitful achievement.

Pacific Coast Society of Obstetrics and Gynecology—The annual meeting of the Pacific Coast Society of Obstetrics and Gynecology will be held in San Francisco November 4-5, under the presidency of Dr. C. Frederic Fluhmann, San Francisco. Among the speakers will be:

- Dr. Howard C. Stearns, Portland, Ore. Extraperitoneal Cesarean Section: Analysis of a Short Series.
- Dr. Ernest W. Page, Berkeley, Calif. The Metabolism of Histidine During Pregnancy.
- Dr. Karl L. Schaepp, San Francisco. Unusual Case of Abdominal Pregnancy.
- Dr. Goodrich C. Schrauffler, Portland. Women in Heavy War Industries: Gynecologic and Obstetric Aspects.
- Dr. Albert V. Pettit, San Francisco. The Closure of Lower Abdominal Incisions.
- Dr. Frederic M. Loomis, Sausalito, Calif. De Senectute: The Good That We Would We Do Not the Evil That We Would Not That We Do.
- Carl G. Hartman, Ph.D., Baltimore. Securing Monkey and Human Embryos.

Another feature of the meeting will be a symposium on Erythroblastosis Fetalis. Dr. Herbert M. Evans, Berkeley, and Charles H. Driforth, Ph.D., Stanford University, will discuss Story of Implantation in Primates.

Association of American Medical Colleges—The fifty-fourth annual meeting of the Association of American Medical Colleges will be held at the Hotel Statler, Cleveland, October 25-27, under the presidency of Dr. Waller S. Leathers, dean

of the Vanderbilt University School of Medicine, Nashville. Speakers on the program will include:

- Dr. Henry E. Meleney, New York. Tropical Medicine Fellowships of the John and Mary R. Markle Foundation.
- Brig. Gen. George F. Lull and Col. Francis M. Fitts, M.C.U.S. Army. The Army Specialized Training Program.
- Comdr. Bartholomew W. Hogan (MC), U.S. Navy. The Navy V-12 Program.
- Dr. Victor E. Johnson. Secretary, Council on Medical Education and Hospitals. American Medical Association, Chicago. Effect of the Accelerated Program of Medical Schools on the Curriculum, Faculty and Students.
- Dr. Willard C. Rappleye, New York. Postwar Planning for Medical Education.
- Dr. Lester J. Evans, New York. The Place of the Small Community Hospital in Postwar Medical Education.
- Dr. Allan Gregg, New York. Can Excellence be Learned?
- M. B. Harrower, Erickson, Madison, Wis. The Rorach Test.
- Philip A. Shaffer, Ph.D., St. Louis. A Recipe for a Medical School.
- Dr. Carey P. McCord, Detroit. Some Aspects of Medical Education in Industrial Health Conservation.
- Dr. Joseph T. Wearn, Cleveland. Present Methods of Medical Teaching.
- Dr. Carl J. Wiggers, Cleveland. Correlation of Physiology Instruction with War Problems.

Aero Medical Association Meeting—The fifteenth annual meeting of the Aero Medical Association of the United States will be held in the Netherland Plaza Hotel, Cincinnati, October 26-27. Among the speakers will be:

- Dr. Albert J. Herbolzheimer, Washington, D.C. The Role of Extraocular Muscles in the Aviation Physical Examination.
- Dr. William J. Holmes, Honolulu, Hawaii. Night Vision, Fundamental Considerations.
- Dr. Whitman C. McConnell and Dr. Whitman H. McConnell, St. Petersburg, Fla. Neuropsychiatric Aspects of the Civilian Pilot Examination.
- Dr. Edgar E. Poos, Detroit. Allergy of the Upper Respiratory Tract.
- Dr. Ralph Bretney, Miller, Washington, D.C. Emerson Day, Baltimore. LeMoine White, Walpole, N.H. and John M. Baldwin, New York. Medical Problems in an Overseas Air Transport Service.
- Lieut. Comdr. Marion M. Kalez (MC), U.S. Naval Reserve. Observations on the Odd and Strange in the South Pacific.
- Brig. Gen. Eugen I. G. Reinartz, M.C., U.S. Army. Observations on Aviation Medicine in the European and African Zones.
- Lieut. Col. Richard L. Meiling, M.R.C., Air Evacuation of Casualties.
- Dr. Alberto Hurtado, Lima, Peru. Comparative Studies Among Flight Personnel and Residents in the Peruvian Andes.
- Major Herman S. Wigodsky, M.R.C. Army. Air Forces Altitude Training Program.
- Lieut. Comdr. Earle E. Metcalfe (MC), U.S. Navy. Navy Low Pressure Chamber Instructional Program.
- Lieut. Comdr. John W. Jenkins, H.V. (S), U.S. Naval Reserve. Prediction of Flight Training Performance by Biographic Data.
- Major Arthur B. Welton, V.C. A.L.S. Selection of Pilots by Means of Psychometric Tests.
- Lieut. Comdr. Ashton Grabbie (MC), U.S. Naval Reserve. Fatigue as a Problem in Aviation Training.
- Squadron Leader K. Evelyn, R.C.A.F. Ottawa, Ont. Night Vision.
- Capt. George M. Haas, M.C.A., U.S. Army. Aircraft Injuries.
- Major F. G. Hall, A.C.A.L.S. and Alice Brues, Ph.D., Dayton, Ohio. Simultaneous Measurements of Pulse Rate, Pulmonary Ventilation and Inspiratory Pressure.
- Comdr. Chalmers L. Gemmill (MC), U.S. Naval Reserve. The Testing of Oxygen Equipment.
- Col. Gustave E. Ledfors, M.C., U.S. Army. Progressive Changes in Medical Field Equipment.
- Capt. Bertram Groesbeck Jr. (MC), U.S. Navy. Modern Trends in the Teaching of Aviation Medicine.
- Lieut. Comdr. Herman J. Sternstein (MC), U.S. Naval Reserve. The Effect of Nasal Ventilation on Tubal Equalizing Efficiency in Flying Personnel.
- Air Commodore I. W. Tice, R.C.A.F. Ottawa, Ont. Current Medical Developments in the Royal Air Forces.
- Capt. John C. Adams (MC), U.S. Navy. Developments in Naval Aviation Medicine.
- Brig. Gen. David N. W. Grant, M.C., U.S. Army. Medical Service with the Army Air Forces.
- Dr. William R. Stovall, Washington, D.C. Trend in Civil Aviation Medicine.
- Lieut. Albert Darnon, A.C.A.L.S. The Importance of Human Sizing Standards in Aviation.
- Capt. Alvin M. Cahan, M.C., A.L.S. The Improved Methods of Resuscitation.
- Lieut. Col. William R. Lovelace II, M.R.C. Aviation Medical Research in Aircraft at High Altitudes.

Another feature of the meeting will be a civil aeronautics medical forum Wednesday with Dr. Stovall in charge.

Government Services

Dr. Wilder Resigns from Food Administration

Dr. Russell M. Wilder has resigned as chief of the civilian food requirements branch of the Food Distribution Administration to return to his activities at the Mayo Clinic, Rochester, Minn. He will continue to serve as medical adviser to the administration. According to the *Washington Post*, September 19, Norman Leon Gold, Silver Spring, Md., assistant to the administrator of agricultural marketing administration, U.S. Department of Agriculture, will become acting chief of the branch.

Diphtheria Problems

The Exec. Group of the Society of Medical Officers of Health has issued an important memorandum on diphtheria problems. Artificial immunization has much reduced the incidence of the disease and minimized its severity. But the variation in the classic signs has increased difficulty in diagnosis, and without evidence of complete immunization, as shown by a negative Schick test, immunity cannot be safely assumed. Further, diphtheria may occur, though rarely, in a Schick-negative person. There is a tendency to place undue reliance on the swab examination. The bacteriologist cannot distinguish between active diphtheria and the carrier state. Doubtful cases must be examined for hemolytic streptococci and Vincent's organisms. Antitoxin must be given at the earliest possible moment, normally in a hospital, as a maximum dose is advisable rather than a series of smaller ones. Only when there has been delay or is likely to be delay should the physician give antitoxin. Antitoxin need not be withheld for fear of severe reactions. The modern protein digested concentrated product rarely gives rise to serum sickness or related phenomena.

In case of doubt continuous observation is necessary and the patient should be sent to a hospital. The procedure today in many hospitals is as follows: 1. When delay in administering antitoxin would be dangerous it should be given immediately before any bacteriologic investigation. 2. When delay of six hours would not be dangerous the Schick test should be performed, swabs taken and antitoxin given six hours later. 3. When delay of one day or more would not be dangerous, antitoxin should be deferred until the results are known. In no case should reliance be placed on the swab alone; every suspected patient when first seen must either receive antitoxin and have the throat or nose swabbed or must be given the Schick test and have the throat or nose swabbed. When there is doubt, antitoxin should be given.

A person whose throat or nose is swabbed because of contact with a diphtheria patient but who has no symptoms must not be classed as having diphtheria, notified or sent to a hospital merely because of a positive finding. Routine swabbing of contacts, except in special circumstances, such as institutional outbreaks, is to be deprecated and should at any rate be restricted to those showing an unhealthy condition of the nasal or pharyngeal mucosa. The waste of time, effort and material is not justified by the occasional discovery of a healthy carrier.

Blind Factory Workers

The Ministry of Labor and National Service has a list of more than eighty occupations in which blind persons have been placed. During the past twelve months over 700 blind men and women have been given jobs formerly done by sighted workers. It is claimed for the blind that they often show unusual powers of concentration and have supersensitive hearing and touch. Keeness of hearing is known to enable a blind operative to detect a blunted cutter or a slight irregularity in the running of a machine which another person would miss. For the most part the blind are given simple process work for which little, if any, preliminary training is needed. But a good many have proved capable of doing intricate assembly work.

What is the accident risk among blind workers? The general experience of blind welfare officers is that the blind factory worker is more than ordinarily careful and that the risk of

accident is negligible. The chief insurance companies do not refuse blind persons, nor do they increase the premium for a blind worker provided the employer can assure them that the work is within the worker's capacity.

On the staff of the Ministry of Labor there are eleven blind shorthand typists and fifty blind telephonists. Many men blinded in the last war are still capable of work. Some months ago the works manager of a London factory inquired urgently of the employment exchange for four men of a particular type. "I must have some one," he said, "for it is an important job though simple. I could do it with my eyes shut." There was no one on the register and the exchange manager suggested that he might engage some blind men. The trial was so successful that a week later he engaged four more.

A New "Ophthalmic" Camera

Wing Commander Harold Pearce, director of photography at the Royal Canadian Force headquarters, has been elected a fellow of the Royal Photographic Society of Great Britain for his part in the invention of a new "ophthalmic" camera developed by that force for studying vitamin deficiencies revealed by the eye. As a result of studies with the camera the medical officers of the force have shown that airmen who finish flights rubbing their eyes, which feel tired and watery, often suffer from a lack of vitamin B₂, or riboflavin. In order to inspect men's eyes and obtain a permanent record of examinations, a special camera was designed by Wing Commander Pearce and Flying Officer M. J. Sym, an authority on microscopic camera work at the University of Manitoba, who worked out the technical details for a 2,000,000 watt bulb which flashes for a split second into the eye camera.

British Medical Aid for China

The British Red Cross Society sent last year a hospital unit of twenty-one persons—doctors and nurses—for service in China. It was under the direction of Dr. W. S. Flowers and established a base hospital at Changsha, Hunan, where sick and wounded, both civilian and military, are being treated and excellent work is being done. In the medical press Lord Horder states that an appeal has been received by the War Organization of the British Red Cross for reinforcements. It is stated to be especially desirable that applicants should have a knowledge of the Chinese language or a background of Chinese experience. Further particulars may be obtained from Dr. H. Gordon Thompson, War Organization of the British Red Cross, 14 Grosvenor Crescent, London, S.W. 1.

C. J. S. Thompson, Medical Historian and Curator

The death of C. J. S. Thompson, Ph.D., has removed an important figure from the medical world, though he was not a member of the medical profession. Born in 1862, he devoted his early days to the study and practice of chemistry and pharmacy with special attention to history. In 1900 he was appointed curator of the projected Wellcome Historical Medical Museum. Until his retirement in 1926 he threw all his energy into gathering and organizing that unrivaled collection. In the course of his work he traveled extensively in Europe. In 1927 the Royal College of Surgeons appointed him honorary curator of the historical section of its museum. He worked at this until the collection was almost completely destroyed by German bombing in 1941. Fortunately he had then completed his great work, "The History and Evolution of Surgical Instruments," which was published last year in New York and which is a permanent record of some of the most important exhibits of the museum. His lifelong study of toxicology gave rise to "Poisoners," a standard reference work on the history of poisoning. Other important works from his pen were "The Apothecary" (1929) and "The Secrets of Magic" (1937).

Mortality in Laryngectomy

Drs Robert C Ferrari and Edgar Flemming recently read an article before the Argentine Academy of Surgery on the surgical results of laryngectomy in 193 cases which were classified in four different groups on the basis of mortality rates. 1 Endolaryngeal cancer with neither tracheal obstruction nor complications and associated diseases in young and strong patients. Twenty-four cases were included in this group, and there was no surgical mortality. 2 Endolaryngeal cancer with tracheal obstruction, with or without previous tracheotomy, including cancer of the epiglottis and cancer with involvement of the pharyngeal wall. Patients in this group were between 50 and 60 years of age, in good general condition. One hundred and ten cases were included in this category. The mortality was 37 per cent. 3 Cancer of the epiglottis with involvement of the tongue and laryngeal cancer with destruction of the larynx and involvement of the surrounding soft tissue. Moderate doses of x-rays were given. The patients were over 60 years of age, in poor general condition. Forty-nine patients were classified in this group. Twelve patients died. 4 Cancer heavily irradiated including laryngeal carcinoma in patients with associated diseases such as diabetes, nephrosclerosis and chronic pulmonary or cardiac conditions. Nine cases fell in this group. The surgical mortality was 45 per cent.

Public Health in Uruguay

Dr Mussio Fournier, minister of public health in Uruguay, has published an extensive study on the activities of this service in the last four years. Several departments were considerably improved. The development of the Center of Prophylaxis and Study of Hydatid Disease deserves special mention because of the importance of this disease in Uruguay. The intensification of the antituberculosis campaign has led to an increase of 130 per cent in the number of beds reserved for tuberculous patients (from 1,555 beds in 1937 to 2,437 beds in 1942). The newly created service for mass radiologic chest survey has examined 50,000 persons in two years. Eight new tuberculosis sanatoriums and several outpatient clinics were established. There are large new pavilions for patients with mental disease with a capacity of 1,000 beds in the Colonia Bernardo Etchepare. The crusade against trachoma is intensified throughout the country. The Department of Industrial Hygiene, the Instituto de Otopedia y Traumatologia, the Centro de Proteccion al Cardiac and four polyclinics of mental hygiene were also established. A total of 7,500,000 pesos was spent in these improvements and new departments. The Department of Public Health had a total of 12,777 beds available in 1942. The Vital Statistics Department of Public Health was reorganized and modernized. A new Department of Public Help to the Poor was recently created. It is mostly concerned with carrying on investigations in order that the poor may receive necessary medical care. The Dorrego laboratory was also created recently for the preparation of drugs for the hospitals of the country at moderate cost.

Allergy

Drs Guido Ruiz Moreno, Miguel A Solari and Alois A Bachmann studied 733 clinical reports of patients who were cared for in the Instituto de Investigaciones Físicas Aplicadas a la Patologia Humana, a department of the National Academy of Medicine of Buenos Aires. The most frequent allergic syndromes were asthma (431 cases), rhinopathies (360 cases) and urticaria (41 cases). The best therapeutic results were obtained in allergic rhinopathies. 69.5 per cent of allergic rhinopathies and 62.1 per cent of allergic asthma were cured. The specific

therapy failed in 18 per cent of the cases of rhinopathy and in 4.5 per cent of those of asthma. There were 62.9 per cent multiple sensitivities and 37.1 per cent single sensitivities. Cutaneous sensitivity was not an index of clinical sensitivity. The greatest frequency of the latter is that which is produced by inhaled substances. 50 per cent. Food is the cause of reaction in 29.8 per cent of the cases, pollen in 11.7 per cent and bacteria and mushrooms in 8.5 per cent. House dust and feather dust were the causes in a large number of instances. Streptococci and staphylococci were the cause in about the same number of instances. Aspergillus in the group of mushroom sensitivities and Ambrosia tenuifolia in that of pollens followed, but the gramineous plants were the most frequent in their groups. Allergic foods in order of frequency were milk, eggs, wheat, fish and pork. It was also found that peas, lentils, rice and beef have allergenic properties. Heredity appeared to be a factor in 69.1 per cent of the cases. Rhinopathies complicated by asthma were observed in 51.9 per cent of the cases. Asthma occurred in about the same number of women as in men. Rhinopathies, urticaria, eczema, headache and conjunctival diseases occurred more frequently in women than in men. Plurisymptomatic allergy was rare. Gastrointestinal syndromes were frequently observed in men. The allergic syndromes appeared most often between the ages of 20 and 29 years and less frequently in these under 9 years.

New Medical Journals

Revista de la Asociacion Argentina de Dietologia is the name of a new medical journal which has recently appeared here. It is the organ of the Instituto Nacional de la Nutricion, Buenos Aires. Dr Pedro Escudero, head of the institute, is the editor. The first issue, of 84 pages, contains articles on determination of the effect of potassium bromate on the content of thiamine (vitamin B₁) in bread, staphylococci as cause of food poisoning, food value of araucaria cones, postwar formulas for feeding children, chemical constitution and vitamins in dehydrated eggs and chemical constitution of food prepared in Argentina (according to results of analysis carried on in the Instituto Nacional de la Nutricion).

Revista de Psicoanalisis is the official organ of the Argentina Association of Psychoanalysis, which is a branch of the International Association of Psychoanalysis. Its purpose is to make available in Spanish the foreign psychoanalytic literature. The editorial staff includes Drs C E Carcamo, G F Hardoy, A Garma, M Langer, E P Riviere and A Rascovsky. The publication has the support of the Francisco Muñoz Foundation.

Pan American Week on Neuropsychiatry

The Pan American Neuropsychiatric Week, postponed from 1942 to this year, will be held in the Faculty of Medicine of Buenos Aires November 7 to 13. Dr Nerio Rojas will preside. The following physicians have been appointed as official speakers: Drs Arturo Vivado of Santiago, Gonzalo Bosch of Buenos Aires, Honorio Delgado of Lima, Osvaldo Loudet of Buenos Aires, A Austregesilo and Fortes Arz Borges of Rio de Janeiro, Vicente Dimieri of Buenos Aires, Camilo Pavese of Montevideo, Jose Belbevi of Buenos Aires, Samuel Ramirez Moreno of Mexico, Nerio Rojas of Buenos Aires, Julio Endara of Quito and A C Pacheco e Silva of São Paulo. The following official topics will be discussed: Presenile Psychoses, 'Abnormal Personality', Nonsuppurated Acute Encephalitis, 'Conceptions on Schizophrenia', Psychopathology of Hunger in Legal Medicine and Neuropsychiatry of Infections in Latin America.

Brief Items

The Sociedad Argentina de Historia de la Medicina honored the memory of Vesalio on the occasion of the fourth centenary since his famous *De hominis fabrica*.

Deaths

James Franklin Allen † Pittsburgh, Howard University College of Medicine Washington, D. C., 1902, University of Pennsylvania Department of Medicine Philadelphia, 1903, aged 70, died in the Allegheny General Hospital, July 27, of carcinoma of the stomach

Thomas D. Armistead, Roanoke, Va. Medical College of Virginia Richmond 1898, member of the Medical Society of Virginia, formerly city physician and coroner, took part in the establishment of the Burtell Memorial Hospital, where for many years he was on the advisory board, served on the staff and for many years a member of the board of the Roanoke Hospital, aged 69, died August 6 of carcinoma

Clarence Edmund Bair, Braddock, Pa. Western Pennsylvania Medical College Pittsburgh, 1900, aged 71, died, August 3, of valvular heart disease

Christo Petroff Balabanoff, Iacoma Wash. University of the City of New York Medical Department, 1888, aged 84, died August 6

Margaret Banta, Los Angeles American Medical Missionary College Battle Creek Mich. and Chicago 1903, aged 76, died July 20, of uremia pyonephrosis, cystitis and pernicious anemia

George Richard Beddow, Pine Grove, Pa. Temple University School of Medicine, Philadelphia, 1934, member of the Medical Society of the State of Pennsylvania, served for many years as deputy coroner of Pine Grove, aged 35, on the associate staff of the Pottsville Hospital, where he died, August 10, of hypertensive cardiovascular disease

Charles Edwin Beecher † Knoxville, Ill. Northwestern University Medical School, Chicago, 1905, served on the staffs of the Cottage Hospital and St. Mary's Hospital, Galesburg, aged 63, died, July 14, of streptococcal sepsis

Jesse Wilmington Bell † Walhalla, S. C., Bellevue Hospital Medical College, New York, 1892, surgeon for the Southern Railroad, aged 76, died, July 14, of heart disease

Sherman Grant Berry, San Diego, Calif., Marion-Sims College of Medicine, St. Louis, 1893, aged 78, died, July 17

Hugo Edward Betz, St. Joseph, Mich., Bennett College of Eclectic Medicine and Surgery, Chicago, 1896, member of the Illinois State Medical Society, at one time trustee of the Chicago Medical Society, formerly professor of dermatology at his alma mater, superintendent of the Iroquois Memorial Hospital, Chicago, from 1915 to 1924 and formerly on the staff of the Cook County Hospital, Chicago, aged 81, died in Berrien Springs, July 29, of thromboangitis obliterans

John Philip Boland, Chicago, Rush Medical College, Chicago, 1928, commissioned a captain in the medical corps, Army of the United States, June 22, 1942, relieved from active duty Jan. 2, 1943 and dishonorably discharged, Jan. 19, 1943, aged 41, died, January 18, of an overdose of barbiturate poisoning

Edwin C. Bollinger, Toledo, Ohio, Chicago Physio-Medical College, 1894, served on the staff of the Women's and Children's Hospital, aged 72, died, July 27, of heart disease

Arthur Stout Boyett, Buena Vista, Ga., University of Nashville (Tenn.) Medical Department, 1894, Vanderbilt University School of Medicine, Nashville, 1894, mayor of Buena Vista, served as state representative and as chairman of the board of county commissioners, aged 73, died, July 30

Raleigh Virgil Butler, Minneapolis, University of Minnesota Medical School, Minneapolis, 1937, aged 39, died in July

Herbert William Case, East Tawas, Mich., Michigan College of Medicine and Surgery, Detroit, 1904, aged 60, died, July 15, of lobar pneumonia

Charles Ellis Clark, Baltimore, the Hahnemann Medical College and Hospital, Chicago, 1912, served during World War I, formerly on the staff of the Hahnemann Hospital, aged 63, died, July 25, of heart disease

Fred William Compton, Olivehurst, Calif., University Medical College of Kansas City, Mo., 1888, aged 80, died in Marysville, June 10, of coronary occlusion and coronary sclerosis

Thomas John Connor † Arlington, Mass., Boston University School of Medicine, 1922, served on the staff of the Lawrence Memorial Hospital, Medford, aged 50, died in East Sandwich, July 16, of coronary thrombosis

Edgar Parsons Cook, Johnstown, Ohio, Cleveland Medical College, 1897, served in the medical corps of the U. S. Army during World War I, aged 76, died in the Newark Hospital, July 6

James H. Cook, McMinnville, Ore., University of Oregon Medical School, Portland, 1895, formerly a trustee of the Linfield College, aged 79, died, July 3, of heart disease

Pleasant A. Creswell, Columbia, Tenn. (licensed in Tennessee in 1912), veteran of the Spanish-American War, aged 69, died recently of bronchial asthma

Dorwin LeRoy Culver, St. Augustine, Fla., University of the City of New York Medical Department, New York, 1895, aged 81, died, July 29, of hypostatic pneumonia

Louis Frederick Curran † Boston, Tufts College Medical School, Boston, 1917, professor of clinical medicine at his alma mater, member of the National Gastroenterological Association on the staff of the Boston City Hospital, physician in chief at the Carney Hospital, trustee of St. Michael's College, Winooski, Vt., aged 57, died, July 28, of coronary thrombosis

Gustavus Cornelius Darlington, Reno, Nev., Long Island College Hospital, Brooklyn, 1901, member of the Medical Society of the State of New York, served overseas during World War I, aged 80, died, July 28, of pneumonia

Ernest Joseph David, Lowell, Mass., Laval University Faculty of Medicine, Quebec, Canada, 1915, member of the Massachusetts Medical Society, district welfare physician for the city, aged 58, on the courtesy staff of St. Joseph's Hospital, where he died, July 11, of acute coronary occlusion

Charles Wesley Davis, New Castle, Pa., Western Pennsylvania Medical College, Pittsburgh, 1895, aged 76, died, July 27, of congestive heart disease

Homer Augustus Davis, Missoula, Mont., Dartmouth Medical School, Hanover, N. H., 1892, aged 85, died, June 27

Jesse J. Dean, Waco, Texas, Medical Department of Tulane University of Louisiana, New Orleans, 1897, active in the establishment of the Dean Highland school, aged 69, died July 22, of heart disease

Peter De Gaetano, Brooklyn, Long Island College Hospital, Brooklyn, 1914, aged 52, died, July 31

Allen Ross Diefendorf, New Haven, Conn.; Yale University School of Medicine, New Haven, 1896, member of the Connecticut State Medical Society, American Neurological Association and the American Psychiatric Association, served as president of the Connecticut Society of Psychiatry, for many years lecturer on psychiatry at his alma mater, aged 71, died at the New Haven Hospital, July 30, of heart disease

Henry E. Donges, Uvalde, Texas (licensed in Texas under the Act of 1907), aged 81, died in the Merritt Hospital, July 24

Francis Bernard Donohue, Bloomingburg, N. Y., Columbia University College of Physicians and Surgeons, New York, 1901, at one time physician at St. Bonaventure College at Allegany, aged 69, died, July 26

Alexander McGill Duff Sr., Republic, Pa., Western Pennsylvania Medical College, Pittsburgh, 1901, for many years a director of the First National Bank of the Republic, chairman of the medical committee of civilian defense, president elect of the Republic Rotary Club, aged 66, died in the Uniontown Hospital, July 24, of chronic nephritis

Lawrence Francis Dugan, Faribault, Minn., Marquette University School of Medicine, Milwaukee, 1924, member of the Minnesota State Medical Association, aged 45, served on the staff of St. Lucas Evangelical Deaconess Hospital, where he died, July 17, of coronary thrombosis

William Esser, Manning, Iowa, Rush Medical College, Chicago, 1891, aged 86, died in Carroll, June 6, of uremia

William Harrison Finney † Clintonville, Wis., Northwestern University Medical School, Chicago, 1899, served as a captain in the medical corps of the U. S. Army during World War I, for many years physician and surgeon for the Chicago and Northwestern Railroad, donated the building site for Clintonville's public library, which was named for him, aged 68, died in St. Elizabeth Hospital, Appleton, July 25, of gangrenous appendicitis

Chester Arthur Fleger † Ansted, W. Va., Maryland Medical College, Baltimore, 1905, aged 62, died, July 22, of angina pectoris

Edward Samuel Folk † Canton, Ohio, Ohio Medical University, Columbus, 1902, since January 1939 mayor of Canton, formerly president of the city council, member of the board of education and board of health, served during World War I, aged 66, honorary member and in 1937 president of the Aultman Hospital, where he died July 31, of coronary heart disease

Isar Goldofsky Fox, Harlingen, Texas, University of Texas School of Medicine, Galveston, 1924, specialist in radiology by the American Board of Radiology, Inc., president of the

Cameron-Walker Counties Medical Society, member of the State Medical Association of Texas and the Radiological Society of North America, Inc., roentgenologist at the Valley Baptist Hospital, aged 42, died July 15, of acute leukemia.

Morris Frank & Boston Harvard Medical School Boston 1911, counselor of the Norfolk District of the Massachusetts Medical Society, school physician on the staff of the Jewish Memorial Hospital on the associate staffs of the Beth Israel and Washingtonian hospitals, physician for the Selective Service Board during World War I and recently, aged 57, died, June 17, of coronary sclerosis.

Rawley H Fuller, South Boston Va University College of Medicine, Richmond 1905, member of the Medical Society of Virginia, surgeon for the Southern Railroad, aged 64, medical superintendent and owner of the South Boston Hospital, where he died July 24, of cerebral thrombosis.

Charlton Edwin Gamble, Turberville S C, Medical College of the State of South Carolina Charleston 1907, aged 62, on the courtesy staff of the Tuomey Hospital Sumter, where he died, July 10, of hypertension nephritis and cerebral hemorrhage.

Frank R Geiger, Columbia, S C, Tennessee Medical College, Knoxville, 1893, member of the South Carolina Medical Association on the staff of the Columbia Hospital, aged 79, died, July 18, of cerebral hemorrhage.

William Henry George & Albany N Y, Albany Medical College, 1894, served on the draft board during World War I, aged 71, died July 16, of coronary disease.

Maurice Gerstein, Brookline, Mass New York University Medical College New York, 1896, member of the Massachusetts Medical Society, past president of the Norfolk District Medical Society, served as chief surgeon at the Jewish Memorial Hospital and on the courtesy staff at Beth Israel Hospital Boston, where he died, July 13, of myocardial infarction, aged 73.

William Winder Goldsborough, Greensboro Md University of Maryland School of Medicine Baltimore 1901, formerly state senator, served as president of the Caroline County Bank, aged 68, died in Princeton N J, July 13, of carcinoma of the left hand carcinoma of the left side of the chest and chronic myocarditis.

Burton Thomas Gordon & Pompano, Fla Rush Medical College, Chicago 1910, at one time on the staff of St Anne's Hospital, Chicago, aged 58, died in Deerfield Beach July 2, of chronic rheumatic heart disease.

Gus R Griggs, Baird Texas (licensed in Oklahoma in 1908), aged 66, died in June of carcinoma of the lungs.

Charles Raymond Haley, San Augustine, Texas Chicago College of Medicine and Surgery, 1916, first lieutenant in the medical corps of the U S Army during World War I, served as health officer of San Augustine County, aged 54, died recently of carcinoma of the colon.

Henry Brown Hart, Sarasota, Fla Medical School of Maine, Portland 1899, member of the Massachusetts Medical Society, served on the board of the Cape Cod Hospital Hyannis Mass., formerly treasurer of the Barnstable District (Mass) Medical Society, aged 72, died in Bradenton, July 13, of cerebral hemorrhage due to arteriosclerosis.

Dorsey Alford Harwood & Santa Ana, Calif, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906, president of the Orange County Medical Society, aged 63, on the staff of St Joseph Hospital, Orange, where he died July 17, of coronary insufficiency.

Della Hertzsch, Louisville Ky University of Michigan Department of Medicine and Surgery Ann Arbor 1891, member of the Kentucky State Medical Association for many years, served as examining physician for the city schools, aged 82, died in the Norton Memorial Infirmary, July 12, of a fracture of the left hip from a fall and bronchopneumonia.

John Henry Heuser, Louisville Ky University of Louisville Medical Department 1891, member of the Kentucky State Medical Association, served during World War I, formerly on the staff of SS Mary and Elizabeth Hospital for many years, medical examiner for the Metropolitan Life Insurance Company, aged 78, died July 1, of myocarditis.

George Price Hill, Summit Hill Pa Medico-Chirurgical College of Philadelphia 1904, aged 64, died July 9, of pleurisy and chronic myocarditis.

Marie Kirby Hopkins Humphrey, East Rochester N Y University of Michigan Department of Medicine and Surgery Ann Arbor 1900, aged 67, died in the Strong Memorial Hos-

pital Rochester, July 18, of pulmonary embolus due to rheumatic and arterio-sclerotic heart disease.

Henry Creath Kelker, Cleveland Western Reserve University Medical Department, Cleveland, 1903, for twenty-eight years physician for the Cleveland Christian Home, formerly on the staff of the Fairview Park Hospital, served as examiner for the Big Four Railroad, aged 68, died, July 11, of coronary occlusion.

Frank Kenworthy & Pittsburgh, Western Pennsylvania Medical College, Pittsburgh, 1901, a captain in the medical corps of the U S Army during World War I, for many years surgeon for the city department of public safety, served on the staffs of the Western Pennsylvania and Shadyside hospitals, aged 65, died, July 14, of coronary thrombosis.

Jacob H Kerth, San Diego, Calif Medical College of Evansville, Ind 1881, aged 87, died, July 8, of heart disease.

John Ketterle, St Albans, N Y, Bellevue Hospital Medical College New York, 1897, member of the Medical Society of the State of New York, a captain in the medical corps of the U S Army during World War I, aged 70, died, July 9, in the Mary Immaculate Hospital, Jamaica, of carcinoma of the sigmoid.

Adolph Kroll Jr, Passaic, N J, University and Bellevue Hospital Medical College, New York 1916, member of the Medical Society of New Jersey, member of the staffs of the Passaic General and St Mary's hospitals, aged 51, died suddenly July 7, in the Newark induction center of coronary occlusion.

Oliver William Kulp, Davenport, Iowa State University of Iowa College of Medicine, Iowa City, 1896, formerly a captain of Company B, 54th Infantry of the Iowa National Guard, veteran of the Spanish-American War, served on the staff of the Mercy Hospital, aged 68, died July 5, in Iowa City, of coronary embolism and carcinoma of the mouth.

Joseph Philorum Lapointe, Harvey N D, School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal Que. Canada, 1917, served on the staff of the St Aloisius Hospital, aged 52, drowned June 25.

Samuel Elijah Newman & St Louis, Miami Medical College Cincinnati 1902, member and formerly vice president of the American Proctologic Society, on the staff of the Jewish Hospital and City Sanitarium, aged 65, died, July 17, of angina pectoris.

James Joseph Pantone, Portland Ore Long Island College Hospital Brooklyn, 1894, member of the Oregon State Medical Society, formerly medical director of the Oregon State Penitentiary Hospital, Salem, served with the Oregon National Guard Company G, first regiment, aged 81, died, June 19, of carcinoma of the esophagus.

Brantly Fuller Parker, York Pa, Hahnemann Medical College and Hospital of Philadelphia 1903, member of the Medical Society of the State of Pennsylvania, served during World War I, aged 65, died June 28, of gastric carcinoma.

Roy C Pope, Niantic Ill, Michigan College of Medicine and Surgery, Detroit 1901, member of the Illinois State Medical Society, aged 67, died in Boulder Junction, Wis., July 8, of valvular disease of the heart.

Harvey Francis Rawlings & Champaign Ill, University of Louisville (Ky) Medical Department, 1910, served during World War I on the staff of the Mercy Hospital, Urbana and the Burnham City Hospital, aged 59, died in Jacksonville, July 14, of bronchopneumonia.

John Luther Reeves Philadelphia, Howard University College of Medicine Washington D C, 1923, member of the Medical Society of the State of Pennsylvania and the American College of Chest Physicians, on the staff of the Mercy Hospital, aged 43, died July 11, of carcinoma.

Brette Redpath Riley & Benedict Kan Central Medical College of St Joseph Mo, 1896, served as mayor of Benedict and for many years as a member of the board of education, served during World War I, aged 72, died July 16, of coronary embolus.

John Wylie Robertson Coulterville Ill, Beaumont Hospital Medical College St Louis 1889, member of the Illinois State Medical Society, for many years local physician and surgeon for the Illinois Central Railroad Company, aged 81, was killed July 20, when the automobile in which he was driving was struck by a train.

Willard B Robinson Richmond Va Kentucky School of Medicine Louisville 1880, aged 81, died July 4.

Armand Otto Rogers, Ennis, Texas, McHarris Medical College, Nashville, Tenn., 1925, aged 45, died, June 21, of hypertension and myocarditis.

Lurten Roscoe Sayler, Dayton, Ohio, Medical College of Ohio, Cincinnati, 1888, for many years served as deputy recorder of Montgomery County, aged 81, died, July 21, of heart disease.

Joseph Peter Schlaikowski, Wauwatosa, Wis., Marquette University School of Medicine, Milwaukee, 1913, served during World War I, resident physician at the Mundelein Sanatorium, aged 55, died, June 14, of coronary thrombosis.

Henry Alvin Shaffer * Charleston, Ill., the Hahnemann Medical College and Hospital, Chicago, 1903, past president of the Cook-Cumberland Counties Medical Society, served during World War I, formerly health officer, president of the staff of the M. A. Montgomery Memorial Sanatorium, aged 69, died, July 15, of acute psychosis.

John Cresswell Slawson, Orlando, Fla., New York University Medical College, New York, 1898, for many years health officer of the town of Carmel, N. Y., and attending physician of the Lincolnville branch of the New York Catholic Protector, formerly on the staffs of the Saratoga Springs Sanatorium, the Dr. Strong's Inc., Saratoga Springs, N. Y., and the Linton Hospital, Utica, N. Y., aged 66, died, July 13, of chronic myocarditis.

Gilbert Cumin Smith, Louisville, Ky., University of Louisville Medical Department, 1892, demonstrator of analytic chemistry at his alma mater, 1907-1908 and assistant to the chair of chemistry and toxicology 1908-1909, also a pharmacist, aged 74, died in St. Joseph Infirmary, June 27, of carcinoma of the esophagus.

Charles James Smyser, New Wilmington, Pa., Harvard Medical School, Boston, 1897, past president of the Lawrence County Medical Society, member of the Medical Society of the State of Pennsylvania, served during the Spanish-American War and World War I on the staff of the Jameson Memorial Hospital, New Castle, aged 78, died, July 22, of arteriosclerosis.

John Harvey Sparks, Detroit, McHarris Medical College, Nashville, Tenn., 1914, member of the Michigan State Medical Society, aged 54, on the staffs of the Wayne Diagnostic Hospital and the Parkside Hospital, where he died, July 11.

Thomas Frank Staley, Bristol, Tenn., Medical College of Virginia, Richmond, 1900, chairman of the Missionary Emergency Fund, Inc., aged 67, died in the Henry Ford Hospital, Detroit, July 13, of acute yellow atrophy.

Eugene Gillis Steele * Buffalo, Wyo., Albany (N. Y.) Medical College, 1906, member of the Missouri State Medical Association, at one time on the staff of the Santa Fe Coast Lines Hospital, Los Angeles, aged 62, died, July 20, of coronary sclerosis.

Robert Marcus Stith * Seattle, University of Pennsylvania Department of Medicine, Philadelphia, 1899, member of the American College of Chest Physicians, served as a captain in the medical corps with the 69th artillery during World War I, was chief of the division of tuberculosis control of the city health department, served as consultant for the United States Marine Hospital, medical director of the Firland Sanatorium and Isolation Hospital, Richmond Highlands, Wash., aged 68, died, June 22, of cerebral hemorrhage.

Cephas Swanson, Minneapolis, University of Minnesota College of Medicine and Surgery, Minneapolis, 1907, member of the Minnesota State Medical Association, medical examiner for the Selective Service Board number 19, aged 67, on the staff of the Lutheran Deaconess Home and Hospital, where he died, July 20, of cerebral hemorrhage.

Albert B. Sweet, Hopkins, Minn. (licensed in Minnesota in 1880), also a pharmacist, Civil War veteran, aged 93, died in the Veterans Administration Facility, Minneapolis, July 6, of cerebral thrombosis.

Richard Jerome Tanner, Norfolk, Neb., Lincoln Medical College of Cotner University, 1909, at one time known as "Diamond Dick", aged 74, died in a Norfolk hospital, July 2, of an injury received in a fall.

Frank Eugene Towers, Minneapolis, University of the City of New York Medical Department, 1875, past president of the Hennepin County Medical Society, formerly served as county coroner, aged 92, died in the Parkview Sanatorium, June 1, of generalized arteriosclerosis and bronchopneumonia.

Haworth Robert Traver, Buffalo, University of Buffalo School of Medicine, 1917, served during World War I, aged 50, died in the Veterans Administration Facility, Canandaigua, N. Y., July 6, of coronary heart disease.

Harrison Allen Tucker, Brooklyn, Long Island College Hospital, Brooklyn, 1888, aged 78, died, June 28, of heart disease.

Arthur Robert Turner * Norwalk, Conn., Université de Paris Faculté de médecine, France, 1894, on the consulting staff of the Norwalk Hospital, aged 80, died, July 2, of coronary thrombosis.

James Walsh * Cortland, N. Y., New York Homeopathic Medical College and Hospital, New York, 1903, formerly school physician, chief of staff, Cortland County Hospital, aged 73, died, July 31, of coronary thrombosis.

Stephen W. Williamson, Dovesville, S. C., College of Physicians and Surgeons, Baltimore, 1904, aged 72, died in the McLeod Infirmary, Florence, July 14, of myocarditis and cerebral thrombosis.

John Wotherspoon, Seattle, University of Glasgow Medical Faculty, Scotland, 1889, member of the Washington State Medical Association, aged 79, died, July 5, of chronic myocarditis.

Alonzo D. Wright, Coxs Creek, Ky., Kentucky School of Medicine, Louisville, 1886, aged 85, was found dead in bed, July 1.

Justus Gaige Wright, Brooklyn, Long Island College Hospital, Brooklyn, 1899, member of the Medical Society of the State of New York, on the staff of the Carson C. Peck Memorial Hospital, consulting pediatrician to the Cumberland, Prospect Heights and the Brooklyn Nursery and Infants' hospitals, aged 65, died at his summer home in Mattituck, N. Y., July 27.

Goldman McDonald Young * Postell, N. C., Lincoln Memorial University Medical Department, Knoxville, Tenn., 1916, aged 58, died, July 9, of carcinoma of the stomach.

DIED WHILE IN MILITARY SERVICE

William Ambrose Hutchinson, Texarkana, Ark., Tulane University of Louisiana School of Medicine, New Orleans, 1924, served as secretary of the Bowie County (Texas) Medical Society in 1934 and as president in 1938, in 1931 was commissioned a first lieutenant in the medical corps of the Texas National Guard, in July 1932 promoted to captain and in March 1940 became a major, began active duty in the medical corps of the U. S. Army (National Guard) in November 1940, was promoted to the grade of lieutenant colonel in June 1942, had been in command of a hospital at Eritrea, Africa, was killed in an airplane crash in the Middle Eastern area of North Africa, February 23.

William Harris Funk * Captain, M. C., U. S. Navy, Washington, D. C., Johns Hopkins University School of Medicine, Baltimore, 1920, U. S. Naval Medical School, 1921, entered the medical corps of the U. S. Navy in June 1920, served on many assignments in various parts of the world where the Navy maintains its stations, specialist certified by the American Board of Internal Medicine, diplomate of the National Board of Medical Examiners, fellow of the American College of Physicians, aged 50, died, January 6, in Kodiak, Alaska.

Adam George Heilman * Lieutenant Colonel, M. C., U. S. Army, Washington, D. C., University of Pennsylvania School of Medicine, Philadelphia, 1913, U. S. Army Medical School, 1922, served during World War I, entered the medical corps of the U. S. Army as a first lieutenant in 1920, aged 57, died in the Walter Reed General Hospital, August 12, of bacterial (Streptococcus fecalis) endocarditis.

Pascasio Quinones-Chacon * Baltimore, George Washington University School of Medicine, Washington, D. C., 1936, member of the Medical Association of Puerto Rico, began active duty as first lieutenant in the medical reserve corps of the U. S. Army in February 1942, aged 32, was killed in an airplane accident in Puerto Rico, Oct. 1, 1942.

Robert Corkill Quine, San Diego, Calif., Rush Medical College, Chicago, 1935, commissioned a captain and later a major in the medical reserve corps of the U. S. Army, a flight surgeon, aged 41, was killed in an airplane crash at Gunnison, Colo., July 19.

Bureau of Investigation

DANGEROUS TO HEALTH When Used as Directed

[EDITORIAL NOTE.—These abstracts differ from other abstracts of Notices of Judgment issued by the Food and Drug Administration of the Federal Security Agency which have appeared in these pages in that they include reference to the fact that these nostrums were specifically declared to be dangerous when used in accordance with the directions given on the label by the manufacturer. The abstracts that follow are given in the briefest possible form: (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the date of shipment, (4) the composition, (5) the type of nostrum, (6) the reason for the charge of misbranding and (7) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Alcoban—Maffett Sales Corporation Seattle Shipped between Feb 19 and Sept 2 1941 Composition capsules containing emetine hydrochloride in amounts varying from 0.05 to 0.18 grain with ephedrine hydrochloride pilocarpine hydrochloride and milk sugar Misbranded because dangerous to health when used in the dosage and with the frequency and duration suggested on label and because claim on carton "Aid in curbing the liquor habit and similar statements in accompanying circular were false and misleading since this product would not be an appropriate or effective treatment for that purpose—[D D A J F D C 616 February 1942]

Breatheasy Kits and Inhalant—Breatheasy Distributors Inc Seattle Shipped between Nov 27 1940 and April 26 1941 Composition government chemist's reported finding that the product had the activity of 5 per cent synthetic racemic epinephrine hydrochloride Misbranded because dangerous to health when used in the dosage or with the frequency or duration prescribed on bottle label and in accompanying booklet. Also misbranded because statements in booklet gave the impression that the product was a safe appropriate and efficacious treatment for asthma hay fever dermatitis eczema chronic bronchitis and head colds. Further misbranded because carton label failed to bear common or usual names of active ingredients a statement of the quantity of contents and the name and place of business of manufacturer packer or distributor—[D D A J F D C 546 November 1942]

Bromo Caps—Parke Davis and Company Detroit Shipped April 11 1941 Composition in each capsule essentially 23 grains of acetanilid and 4 grains of aspirin and 3/4 grain of caffeine Adulterated because strength differed from that claimed on label namely that each capsule contained 1/2 grains of acetanilid. Misbranded because dangerous to health if used in dosage or with frequency or duration suggested on label. Also misbranded because of misleading name since no bromine or compound thereof was present. Further misbranded because of false and misleading claims that product contained no narcotic drugs and was a quick sure scientific remedy which would take the place of aspirin and habit forming headache powders and liquids since the latter claim created the impression that the product contained neither dangerous drugs nor a poison. Misbranded again because of misrepresentations that the preparation would give relief and constitute an adequate treatment for rheumatic pains colds toothache mental fatigue menstrual pains feverish conditions sea or car sickness or overindulgence in food or drink. Misbranded also because label did not list the common or usual names of the active ingredients other than acetanilid and the quantity or proportion of the latter was not correctly declared. Further charges of misbranding were Labels failed to bear adequate directions for use or warnings that because of acetanilid content frequent or continued use might be dangerous causing serious blood disturbance anemia collapse or dependence on that drug also label did not caution against giving the product to children or using it in those pathologic conditions wherein it might be dangerous to health or warn against unsafe dosage or methods or duration of administration—[D D A J F D C 601 February 1943]

Cold Tablets and Capsules—Lypjohn Company Kalamazoo Mich and New York Shipped between Sept 20 1940 and Feb 14 1941 Composition included acetanilid a quinine salt camphor podophyllin and aloin Products were variously labeled Capsule Cold Special Lypjohn Cold Special Cold Special No 2 and Swiss Capsules All misbranded because dangerous to health when used in dosage and with frequency and duration suggested in labeling. Further misbranded because labeling did not in most instances bear adequate directions for use since such directions as were given would have caused the products to be dangerous to health. Further misbranded because labeling failed to warn sufficiently against use by children and in those pathologic conditions wherein the tablets and capsules might be dangerous to health. Also misbranded because labels failed to caution against use in cases of nausea vomiting abdominal pain or other symptoms of appendicitis or continued use which might cause serious blood disturbances anemia collapse or dependence on the drug. Misbranded finally because of false and misleading representation that the tablets and capsules were a remedy for colds—[D D A J F D C 60 February 1942]

Leunbach' Paste—Merz and Company Chemical Works Inc Newark and East Orange N J Shipped Aug 16 1940 Composition syrup water and about 2 per cent each of alcohol and potassium iodide. Misbranded because dangerous to health when used as an abortifacient in the dosage or with the frequency or duration recommended in labeling—[D D A J F D C 607 February 1943] (Another consignment shipped Jan 25 1942 by the Doctors Pharmacy Milwaukee, was declared misbranded under D D A J F D C 608 for the reason given above.)

Mrs Moffat's Shoo Fly Powders for Drunkenness—M F Groves Son and Company Philadelphia Shipped Nov 2 1940 Composition tartar emetic Misbranded because dangerous to health when used in the dosage or with the frequency or duration suggested in labeling and also because statement for drunkenness was false and misleading—[D D A J F D C 605 February 1943]

Nature's Minerals Compound—Nature's Mineral Company Indianapolis also known as Nature's Minerals Company and Nature's Mineral Food Company Shipped between Aug 26 1940 and Jan 24 1941 Composition (preparation in powder and tablet form) essentially compounds of calcium magnesium iron and sodium phosphate carbonates sulfates chlorides sulfur and fluorine. Misbranded because dangerous to health when used in the dosage or with the frequency or duration suggested in the labeling since it contained a poisonous substance fluorine. Further misbranded because of false and misleading representations on cartons and bottles that the preparation would supply minerals deficient in the ordinary diet [D D A J F D C 541 542 and 543 November 1942] Consignments of a product called simply Nature's Minerals and shipped by the aforementioned concern between Sept 15 1940 and April 18 1941 and reported identical in composition were subjects of D D A J F D C 543 and 544 November 1942 One charge of misbranding was under the representations that the product would be efficacious in treating or preventing cancer arterio sclerosis diabetes stomach blood kidney and bladder disorders gall tones and some other things. Cases Nos 544 and 545 also included the name of P G Jurich Pasadena Calif as a shipper.

Special Formula Tablets and McNeal's Laxative Cold Tablets—Arner Company Inc Buffalo N Y Shipped Dec 16 1940 Composition (the products were identical) in each tablet acetanilid (approximately 1 grain) quinine sulfate (approximately 0.58 grain) a laxative plant drug and a small amount of atropine. McNeal product misbranded because dangerous to health when used in the dosage or with the frequency or duration suggested in the labeling. Also misbranded because labeling failed to give adequate directions for taking it and did not sufficiently caution against use by children or in those pathologic conditions in which it might be dangerous to health or warn against unsafe dosage or methods or duration of administration or application for protection of users. Special Formula Tablets misbranded because labels did not bear common or usual names of the active ingredients or declare the amounts or proportions of acetanilid and atropine present—[D D A J F D C 547 November 1942]

Tabknoll Three Bromides Effervescent—H G Knoll and Company Inc New York Shipped Jan 6 1941 Composition ammonium potassium and sodium bromides Misbranded because dangerous to health when taken in the dosage or with the frequency and duration prescribed in the labeling because latter failed to give adequate directions for use and to bear sufficient warnings against use when it might be dangerous to health or caution against unsafe dosage or duration of administration in such manner and form as are necessary for protection of users—[D D A J F D C 548 November 1942]

Whitehall's (Dr.) Compound Tablets—Dr Whitehall Megrimine Company South Bend Ind Shipped between Nov 27 and Dec 3 1940 Composition acetanilid sodium salicylate and plant material Misbranded because dangerous to health if taken in the dosage or with the frequency or duration prescribed in the labeling since such use might cause serious blood disturbances anemia collapse and a dependence on the drug. Further misbranded because labeling failed to give adequate directions for use since it did not provide for a limit as to the duration or frequency of administration. Misbranded also because labels failed to carry adequate warnings against use by children or in conditions in which the product might be dangerous to health or to caution against unsafe dosage or methods or duration of administration. Misbranded finally because label gave the false impression that the product was an appropriate treatment for the conditions described whereas it was not but actually a dangerous drug—[D D A J F D C 549 November 1942]

Zerbst's Capsules—Zerbst Pharmaceutical Company St Joseph Mo Shipped Jan 20 1941 Composition capsules (in 25 cent package) each containing acetanilid (1 1/2 grains per capsule) with caffeine resorcinol material camphor capsicum aloin and afoetida (0 cent package) acetanilid (2 1/2 grains per capsule) and a laxative plant drug not named. Both packages misbranded because dangerous to health when used according to directions on the label. Further misbranded because labels failed to bear adequate warnings against use by children or in those pathologic conditions in which product might be dangerous to health or to caution against unsafe dosage or duration of administration for protection of users since no warning was given against use in the presence of appendicitis or other conditions with reference to possible serious blood disturbances following use of acetanilid. Further warning that frequent or continued use might result in dependence on the drug. The 50 cent package was found to contain a laxative plant drug not named. It was falsely represented that these capsules were a remedy for colds and label failed to give common or usual name of each active ingredient or declare quantity of each of the same—[D D A J F D C 60 November 1942]

THE EMERGENCE OF THE CHRONIC PATIENT

To the Editor—Of late years the students of vital and social statistics have been calling our attention to the remarkable increase in longevity which is having such a profound influence on our way of living. As the length of our days on earth is increased we find ourselves living longer, in health and otherwise, with people who must live longer with us. Youth, being confronted with the problems of age, must share them. Youth too may be stricken by long-term disease, as in the case of rheumatic fever with its complications and sequelae. Against the satisfaction and joy of preventing and curing illness in the earlier years we now have the specter of the degenerative and malignant diseases which are more characteristic of the later years.

The 'acute' hospital which has chosen and specialized in emergencies during the earlier years of our lives, can have only one response to the needs of the chronic patient with whom philanthropist physician, nurse and social worker must now live longer. We have learned to be patient with the lame, the halt and the blind, and we must learn to be patient with those who are sick with a long-term disease. Medical science is equipped to meet the challenge in this realm and should welcome the opportunity. The beggar must not be turned away from our doors for fear that he may break our hearts.

A reasonable proportion of long-term patients who still require intensive medical care should be retained in general hospitals, and the establishment of independent hospitals for chronic disease, at comparatively greater expense if the job is to be done right, and at a distance, should be discouraged. The qualifying adjectives "acute" and "chronic" have no place in connection with institutions built for the scientific care of the sick. For our help in reconsidering the claims of the long-term patient to the attention of the modern hospital we have a number of recent developments which owe their existence to the war and to the threat of insecurity generally.

Provisions for social security which preceded and subsequently went hand in hand with the idea of the four freedoms include more public funds for the care of patients who are chronically ill and cannot finance themselves. (Poverty and chronic disease lie within a vicious circle which must be broken somewhere.) Furthermore, we are witnessing an extension of voluntary group insurance schemes which will confer more benefits all around, over longer periods of time, for those who can afford it. Direct income from patient sources will also be noticeably increased. For these three reasons, hospitals will be less dependent on philanthropy and ultimately less dependent on voluntary medical service. Because of these new or improved sources of income the financial reason for the transfer of long-term patients from the "acute" hospital to a segregated and isolated institution independently maintained for chronic disease, at a time when they may need scientific care most, will disappear. Such patients will be retained longer in general hospitals, where they belong. The duration of their illness, which now differentiates them so artificially from short-term patients, will no longer appear as a criterion for their admission or retention.

Apart from economic developments which will favor the retention of the long-term patient, we have the following to consider: (a) the increased interest of the physician, social worker and public generally in chronic disease, (b) the provision of full time opportunities in hospitals and the remuneration of physicians for medical service in hospitals and dispensaries

generally, (c) the increase of laboratory facilities in hospitals where qualified physicians who have selective interests in the various categories of chronic disease can develop their special talents along these lines and (d) the utter inadequacy and indecency of existing facilities for the care of long-term patients. Thus the second major reason for transfer will disappear, namely the lack of interest in patients with a long drawn out illness. The presence of these patients in hospitals where they are under control over longer periods of time, either continuously or in divided visits, gives to the scientific physician greater opportunities to study the remote results of treatment than ever before and, if he is freed from financial worry while having the additional opportunities of the laboratory, he will welcome the change. In passing, I might add that the lack of interest of the doctor in chronic disease encourages quackery as a possible relief to the uneducated patient.

These new trends indicate that chronic disease is rapidly emerging as an acute social and medical problem, and it will not be denied if for no other reason because it is beginning to strike home to many of us who are responsible for hospital progress. Moreover, the war will leave us with a demand for the rehabilitation of the wounded in our armed forces, many of whom will be in the long-term classification. This will doubtless increase our respect for the patient suffering from chronic disease and stimulate adequate provisions for his hospitalization.

The medical profession is greatly concerned with the trends of social security in its broadest implications and now has the opportunity of cooperating in the solution of this vexing problem, while benefiting itself in many desirable ways. It is now up to the hospitals and their medical boards to formulate a program without delay. In competition with government, they have always done better in such matters thus far.

E M BLUESTONE, M D, New York

Director, Montefiore Hospital

"INSECT VECTORS OF POLIOMYELITIS"

To the Editor—In reading your editorial on "Insect Vectors of Poliomyelitis" in the August 28 issue of THE JOURNAL I was struck by this statement: "The dominant species in each group were green bottleflies and blowflies, the common housefly being present in small numbers in only two of the four positive specimens."

The common housefly is such an important vector of dysentery that it seemed strange that it had not been more seriously considered in these investigations concerning poliomyelitis. I wondered at once what type of bait had been used in catching the flies used in the experiments by Trask, Paul and Melnick. I had missed their articles in the *Journal of Experimental Medicine*, but on looking up their publication I see that the bait used principally was fish. This bait is somewhat attractive to the housefly, but, of course, much more so to bottleflies and blowflies. Had a fermenting bait been used it is far more than probable that the dominant species of flies caught would have been houseflies, and the results might have been totally different.

Control of the housefly is a major problem in Army sanitation and it is especially important that the role of this insect with respect to the spread of poliomyelitis be made clear. If any experimental work is being done during your current epidemic in Chicago, it is suggested that efforts be made to trap houseflies and repeat the experiments of Trask, Paul and Melnick.

BALTIMORE

It is now common knowledge that the Japanese in taking Java cut off the source of almost the entire prewar quinine supply of the world. It is equally well known that the resulting quinine shortage is still in spite of many ingenious and valuable countermeasures, one of the most serious problems of medical warfare. The American Medical Association can rightly be proud of having been, seventy-five years ago, the protagonist of a plan which if it had been executed, would have saved us our present difficulties.

In 1738, a hundred years after the introduction of the Peruvian bark into our pharmacopeia La Condamine had already foreseen the exhaustion of the South American supply as a consequence of the purely destructive methods of "production" in New Granada, Ecuador, Peru and Bolivia. After a hundred years had passed the situation had grown so dangerous indeed that the Dutch and the English started cultivating the cinchona tree in their own colonies: the former in 1854 in Java, the latter in 1860 in the Neilgherry Hills of southern India.

The Transactions of the fifteenth annual session of the American Medical Association held in 1864 in the city of New York, contain a little memorandum of Dr. D. J. Macgowan (apparently an army surgeon) of Washington, D. C. on the "Naturalization of Cinchona on the Eastern Continent."¹ Macgowan dealt with the Dutch and English experiments and recommended that they also be tried in Haiti. The assembly reacted favorably to the suggestion and on the motion of Dr. J. H. Griscom the famous New York Quaker and sanitarian appointed a committee composed of three of its most distinguished members: Joseph M. Smith, E. R. Squibb and J. H. Griscom to confer with the Haitian minister² on the subject.

Three years later, in 1867 the Medical Society of Wayne County, Mich., submitted to the eighteenth annual session of the American Medical Association a paper of its member Dr. J. M. Bigelow which examined the whole cinchona situation in more detail and boldly and rightly asked the introduction and cultivation of the cinchona trees in the United States.³ Dr. Bigelow designated western Texas, Arizona or Lower California as best fitted for such plantations. On the motion of Dr. W. B. Atkinson (Pennsylvania) a committee consisting of I. M. Toner (District of Columbia), F. Howard (District of Columbia) and C. A. Lee (New York State), was appointed to memorialize Congress on this vital question.⁴ In the next year 1868 Dr. Toner read a report of the committee in the Section on Chemistry and Materia Medica and a new committee, composed of Dr. L. I. Deal (Pennsylvania), T. A. Logan (California) and J. M. Bigelow (Michigan) was elected to memorialize Congress.⁵ For seven years this committee under the leadership of Dr. Deal was to carry on a vigorous, intelligent fight for the cultivation of the cinchona tree in the United States.

At the twenty-first annual session in 1870, Dr. L. I. Deal submitted a report of the committee, consisting mainly of a proposed memorial to Congress.⁶ This memorial was the most important and substantial document published during this action of the American Medical Association. It starts with an explanation of the medical value of quinine and then gives some interesting data on the economic implications of the problem. For example, from 1859 to 1865, \$2,287,250 worth of bark and quinine salts were imported into the United States, between 1861 and 1865 the United States Army purchased 1,198,000 ounces of quinine (the average annual consumption of the United States before World War II was 5,000,000 ounces). The memorial describes the danger arising from the exhaustion of the Peruvian supply and recommends the cultivation of cinchona in California which seemed to be even better suited for such an enterprise than India. The aid of the California State Board of Agriculture and the Sacramento Medical Society had already been secured. The memorial concludes:

The American Medical Association therefore asks in view of the foregoing facts that the Congress of the United States would appoint a commission of scientific men for the following purpose:

1 To determine what portion if any of the public domain of the United States will produce the cinchona and which may be set apart for this purpose.

2 To determine what species may be best transplanted and will furnish the greatest amount of active principles.

3 That they be authorized to visit such South American countries as they may deem necessary in order to determine these points, employ a competent botanist to assist them and that our consuls in such States be instructed to further these investigations.

4 That they be empowered to negotiate for and obtain a proper quantity of seeds and plants.

In 1872 Dr. L. I. Deal reported "a gratifying progress Congress having been memorialized with a favorable prospect of success." A second memorial to Congress was submitted.⁷ The transactions of 1874 contain a more detailed report of the committee which still sounds rather optimistic. Since 1868 "three memorials had been presented to Congress. The last by Mr. Scott of Pennsylvania in the Senate and by Mr. Kelley of Pennsylvania in the House." The latter wrote to Dr. Deal that he could not assure him of speedy help from Congress in the matter but that continuous pushing of the matter would probably result in success. The committee had obtained the support of the Botanical Gardens in Washington, D. C., or the Department of Agriculture and of the Horticultural Society. President Grant in his message relating to the purchase of San Domingo had advanced the argument that the climate and the soil of this island were suitable for the cultivation of cinchona. The committee was continued.⁸

But alas at the twenty-sixth annual session in 1875 after a "report of progress" the committee was discontinued.⁹ We do not know the exact reasons and motivations for this step but though regrettable it is only human that after seven years of incessant endeavor the Association grew tired of preaching to deaf ears and did not like Jacob go on for another seven years of bondage. In this action which seemed only an episode but has now become so consequential the American Medical Association showed a considerable degree of inboardness and of foresight in the public interest. Like so many plans of prevention its plan probably suffered from looking more costly than expedient. The failure seems no reason to give up in similar situations in which our scientific committees recommend unpopular proposals in the public interest. On the contrary it seems to be rather an admonition to be still more persistent. 1909 East Monument Street

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Venereal Diseases Constitutionality of City Ordinance Requiring Treatment of Infected Persons Convicted of Prostitution—By Little Rock city ordinances prostitution is made a criminal offense and the city health officer is required to ascertain by necessary tests and examinations whether or not a person convicted of prostitution has any venereal disease. Any evidence so acquired is not to be used in any criminal prosecution against the person convicted. If the convicted person is found to have a venereal disease in a communicable stage and if she fails to take or submit to treatment adequate for the protection of public health, the city health officer is authorized to commit her to an appropriate institution for treatment, provided only that she can be committed without endangering life. The plaintiff was convicted of prostitution and was thereafter examined by the city health officer and was found to have venereal disease in a communicable stage. She was thereafter ordered quarantined in a health center maintained by the United States government in Hot Springs, Ark. She then filed a petition for a writ of habeas corpus, contending that her detention was illegal because the ordinances purporting to authorize it were unconstitutional and void. The trial court granted the writ and the defendants, the city of Little Rock, the city health officer and the county sheriff, appealed to the Supreme Court of Arkansas.

The determining question here presented, said the Supreme Court, is whether or not the ordinances of Little Rock in question are valid as being within the police power of the city. Admittedly, the city has power to declare prostitution a criminal offense. The proceeding under which the plaintiff was detained is not a criminal proceeding, however, but is one in the interest not only of the plaintiff but of the public. It is a proceeding to compel her to be quarantined and segregated from the public to the end that she may be cured of the venereal disease with which she is infected and thus not communicate it to others. When a cure is effected the authority to detain her is at an end. Courts, the court continued, in testing the validity of a regulation, must resolve all doubts in favor of the legislative action and must sustain the regulation unless it appears to be clearly outside the scope of reasonable and legitimate regu-

lation. The police power of the state is founded in public necessity and this necessity must exist in order to justify its exercise. It is always justified when it can be said to be in the interest of the public health, public safety and public comfort, and in such instances private rights must yield to their security under reasonable laws. Can there be any doubt that the legislature might enact valid legislation similar to the ordinances here in question? We think not. If it could, then it can and has delegated this power to municipalities. Section 9543, Pope's Digest, authorizes municipalities to make ordinances to provide for the safety, preserve the health, promote the prosperity and improve the morals, order, comfort and convenience of the inhabitants thereof. Section 9589 further gives municipalities power to prevent injury or annoyance within the limits of the corporation, from anything dangerous, offensive or unhealthy. These two sections constitute a delegation to municipalities of the state's power to legislate in protection of public health. Exercise of the delegated powers by the city in the ordinances here presented must be held to be within the grant, unless it can be said that the power conferred on the city health officer is unreasonable. The court could not say that the power conferred on the health officer was "clearly outside the scope of reasonable and legitimate regulation."

Section 9679, Pope's Digest, authorizes a city council to establish a board of health, with jurisdiction for 1 mile beyond the city limits, and for quarantine purposes, in cases of epidemic, 5 miles. The trial court held that that statute denied the city health officer the right to quarantine plaintiff outside the city or county beyond the limits indicated in the statute. The statute referred to, said the Supreme Court, simply means that the jurisdiction of the health officer extends for 1 mile beyond the city limits, or for 5 miles for quarantine purposes, in cases of epidemics. It has no reference to the place a person may be confined for quarantine purposes, but only to the extent of the jurisdiction beyond the city limits for the better protection of the inhabitants of the city. Section 6438, *ibid*, expressly requires the city health officer to perform the duties prescribed for him by the regulations of the state board of health. A regulation of the state board of health, promulgated under that authority, provided that any health authority should, when in the exercise of his discretion he believed that the public health required it, commit any person apprehended, examined and found afflicted with an infectious disease and who refused or failed to take treatment adequate for the protection of the public health to a hospital or other place in the state for such treatment if the commitment could be done without endangering the life of the patient. This regulation, the court concluded, was authority to commit the plaintiff outside of Little Rock and to confine her where she was confined in Hot Springs.

The Supreme Court accordingly reversed the judgment of the trial court and remanded the plaintiff to the custody of the sheriff for isolation and quarantine.—*City of Little Rock v. Smith*, 163 S. W. (2d) 705 (Ark., 1942)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1953 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Studies on Bone Marrow in Vitro—Rachmilewitz and Rosin obtained bone marrow from the tibias of 6 to 8 week old rabbits. The containers used for explantation were glass tubes 15 cm in height and 8 mm in diameter. The bone marrow fragment of the size of 3 cubic millimeters was placed immediately after removal from the tibia in the medium consisting of 3 drops of rabbit's plasma 3 drops of Tyrode solution and 1 drop of diluted chick embryo extract. The tissue fragments were planted at the time when the plasma began to coagulate so that they remained suspended in the upper layers of the medium. The tightly closed tubes were incubated at 37°C. After incubation the plasma clot containing the bone marrow explant was removed and fixed. Experiments were carried out with bone marrow of 26 rabbits. The bone marrow of 12 animals showed predominant leukopoiesis of S predominant erythropoiesis. In the bone marrow of 6 animals myeloid and erythroid cells were present in nearly equal proportions. The material was fixed in Zenker's and Hell's fluid. After the specimens had been embedded in celloidin paraffin serial sections 4 microns thick were made and stained with hematoxylin-eosin. Some of the sections were stained with Giemsa stain. The object of this investigation was to establish a physiologic model which would help in the analysis of the factors which govern

normal and pathologic blood cell formation in the bone marrow. The method of bone marrow explantation and the observations made give reason to assume that this may be possible. The bone marrow in vitro continues for a certain period of time the specific functional activity, even at an increased rate. This period of functional activity of bone marrow in vitro can be made use of in the study of the factors which affect the bone marrow function. Maturation and multiplication of white and red cells was observed to take place in the explanted bone marrow, maturation of polymorphonuclear leukocytes in vitro was proved by differential cell counts. The period of functional activity of the explanted bone marrow is followed by depletion of the marrow parenchyma and fibroblastic proliferation of the stroma.

Cytotoxicity of Bactericidal Agents—In order to compare the relative cytotoxic effect of tyrothricin and its fractions gramicidin and tyrocidine, Herrell and his collaborators made experiments in which tissues were grown in a plasma clot in Carrel flasks for a period of four days. Rabbit spleen was used as a source of tissue because it is fairly homogeneous and provides a good source of large wandering cells or macrophages. The authors conclude that when the toxicity of the products of *Bacillus brevis* is determined by their ability to inhibit the migration of macrophages from the normal rabbit's spleen in a medium composed of serum, plasma and chick embryo extract, it appears that gramicidin is most toxic, tyrothricin is next in order of toxicity, and tyrocidine is much less toxic than either gramicidin or tyrothricin. The greater part of the cytotoxicity of tyrothricin is accounted for by its content of gramicidin. The authors emphasize that the cytotoxicity of products of *B. brevis* is low compared with that of a number of other germicides. This agrees with the absence or deleterious effects on the tissues when aqueous suspensions of these substances are used in the local treatment of infections.

Obesity and Appetite Control—According to Colton and his associates the restriction of food intake is still the basic principle in all successful attempts at treatment. Dietary restriction over a long period of time is exceedingly difficult in most cases without the aid of some agent that depresses the appetite. The authors treated 300 cases of obesity by dietary restriction and appetite control. Appetite was best controlled by dextroamphetamine, although amphetamine and propadrine hydrochloride were found to be effective. Treatment was aimed at correcting eating habits so that the patient would have less desire for the high caloric foods. Various therapeutic agents (thyroid ammonium chloride salyrgan-theophylline and decholin sodium) were added successively to eliminate each refractory period. The average weight loss for the entire group for the therapy was 2 pounds (0.9 Kg) a week. The greatest weight loss was during the first month of therapy and averaged 2½ pounds (1.1 Kg) a week.

Colored Reflex from Lens in Mercurialism—Attention is directed to a brownish reflex from the anterior capsule of the lens which occurs in cases of chronic mercurialism. The reflex may be found also in those who have been exposed for a long time with mercury or in an atrophic retinopathy secondary to a long

they may exhibit no symptoms of mercurialism. The reflex has not been observed in other patients nor has any previous report of such a reflex been found in the literature. This hitherless, somewhat homogeneous looking reflex from the interior capsule of the lens is seen well with the slit lamp when a low power objective is used. When examined with oblique illumination the lenses of the eyes in which the colored reflex is pronounced present a dull gray appearance. The colored reflex, which is believed to be a deposit of mercury on or in the interior capsule, does not disappear after the symptoms of chronic mercurialism subside or when the individual discontinues work with mercury. Some patients were examined ten and twenty years after they had last worked with mercury and the reflex was still as vivid as that which is seen in active workers who have symptoms of chronic mercurialism. Seventy persons who are or had been engaged in the manufacture of thermometers in which mercury is used were examined. One patient who had worked as a coner in the felt hat industry for over thirty years also was examined. This man exhibited definite symptoms of chronic mercurialism and a pronounced colored reflex from the interior capsule. The colored reflex was present in 37 or over one half of the cases examined. Fourteen of the 71 manifested symptoms of chronic mercurialism, and in all of these cases the reflex was present. The author suggests that the colored reflex from the lens is a permanent and probably an early diagnostic sign of chronic mercurialism.

Effect of Caffeine and Coffee Extract on Activity of Digestive Enzymes—Walker investigated the effect of caffeine and coffee extract on the activity of the digestive enzymes in vitro. The enzymes studied were those which act on carbohydrates, proteins and fats in the digestive tract, namely ptyalin, pancreatic amylase, pepsin, trypsin and pancreatic lipase. It was found that caffeine in concentrations of 20 mg and 40 mg per hundred cubic centimeters of substrate has no effect in vitro on the saccharogenic action of salivary and pancreatic amylases, nor does it affect the digestion of casein by pepsin and trypsin or of olive oil by pancreatic lipase. Coffee extract in the two concentrations studied does not affect the digestion in vitro of casein by pepsin or trypsin. It increases the rate of digestion of starch by the salivary and pancreatic amylases. It retards the digestion of olive oil by pancreatic lipase.

- Comparison of Nasopharyngeal Swab and Cough Plate in Diagnosis of Whooping Cough and Hemophilus Pertussis Carriers J. J. Miller Jr., C. W. Leach, T. M. Saito and J. B. Humber—p. 839

Danger of Botulism—According to Hall a recent tabulation shows that during the period 1899 to 1941 as many as 359 outbreaks of botulism with 1,024 cases and 669 deaths were recorded in the United States and Canada. Most of these outbreaks were caused by eating improperly home-canned vegetables. In view of the current plans of many housewives to can as much food as possible, a timely warning may help to prevent a recurrence of the catastrophic outbreaks of botulism which followed the widespread use of the "cold pack" method of home canning during the first world war. This is primarily a problem in public education of housewives and others engaged in canning and serving foods. It is recognized that while the pressure cooker, properly operated, provides the easiest and best method of home canning there is likely to be a shortage of such cookers. Correct operation should be emphasized. The author has recorded three outbreaks of botulism caused by foods supposed to have been sterilized in pressure cookers. He stresses the selection of sound produce, careful cleansing, blanching when indicated, general cleanliness, correct application of intermittent sterilization and the use of other methods of preserving food, notably drying, salting and pickling, in which there is little or no danger from botulism. With regard to consumption the author stresses the significance of turbidity, gas production, softening and odor as criteria of spoilage, the danger of eating or even tasting freshly opened home-canned foods, especially if signs of spoilage are present, the fact that certain foods, notably beets, chili, some times beans, and possibly other foods, may show no easily recognizable signs of spoilage even though botulinus toxin is present, the importance of the destruction of botulinus toxin by boiling home-canned foods for at least five minutes before serving, the harmlessness of the spores of *Bacillus botulinus*. Contaminated foods should be boiled in strong lye water to avoid killing poultry and other domestic animals, excessive pollution of the soil with the spores of *Bacillus botulinus* and loss of usable containers. The author stresses prompt reporting of suspicious symptoms to physicians and the saving of remnants of food for epidemiologic and laboratory studies of food poisoning.

Weil's Disease and Meningitis—Clapper and Myers report 15 cases of Weil's disease. In 2 both clinical and laboratory evidence of meningitis was observed, in 7 there was an abnormal cellular reaction in the cerebrospinal fluid without clinical signs of meningeal irritation and in 1 meningitis was present without the cerebrospinal fluid showing pleocytosis.

Cell counts on the cerebrospinal fluid may reach 1,000 or more per cubic millimeter. Polymorphonuclear cells predominate early and lymphocytes later. The dextrose content of the cerebrospinal fluid is not altered. Yellow discoloration of the cerebrospinal fluid is common in Weil's disease. It is at least in part due to bilirubin. Retention of urea is frequent. Pericarditis, auricular fibrillation or disturbances of conduction may occur in hearts previously normal. The plasma prothrombin, although appreciably decreased in most instances, usually does not reach levels sufficiently low to account for the hemorrhagic manifestations. Anasarca, the result of hypoproteinemia, may develop. Immunotransfusions may be of value in treatment and are worthy of a more extended trial.

Mixtures of Protamine Zinc and Unmodified Insulins—According to Hildebrand and Rynearson most authors have agreed that for satisfactory control of severe diabetes mellitus protamine zinc insulin must be supplemented by unmodified insulin. The use of mixtures was first proposed by Lawrence and Aitken in 1938. At the Mayo Clinic mixtures of the two types of insulin have been used in the routine treatment of severe diabetes and proved satisfactory for a large proportion of diabetic patients. There are cases in which adequate control has been difficult and the question of adjusting the amounts of each type of insulin has not been answered. The authors studied the effects of injecting various mixtures. Observations were made on 2 young women with severe diabetes. The results of a study of the dosage of insulin in 100 cases of diabetes taken at random from the files are included. The disease in these cases was severe enough to require administration of a mixture of the two types of insulin. The authors have not been able to demonstrate that any one ratio of the protamine zinc insulin to unmodified insulin gave an optimal effect. However ratios of protamine zinc insulin to unmodified insulin which lay between the two extremes of 1:1 and 1:5 gave the most satisfactory control, mixtures in which the ratios of protamine zinc insulin to unmodified insulin were 1:2, 1:3, 1:4, 2:3 and 2:5 were capable of adequate control of the blood sugar during the twenty-four hours after their injection. The use of a mixture of equal parts of the two insulins resulted in blood sugar curves very similar to those obtained when the dose consisted of protamine zinc insulin alone. On the other hand, a mixture of 1 part of protamine zinc insulin to 5 parts of unmodified insulin resulted in an immediate hypoglycemic effect such as might follow the injection of a large dose of unmodified insulin alone. Injection of the two types of insulin at separate sites gave not as satisfactory control of the blood sugar level as their injection together. The authors tried to eliminate the midmorning lag in hypoglycemic effect of the mixtures of the two insulins by injection of the dose of insulin one hour instead of half an hour before breakfast. Although this method eliminated the lag it did not result in smoother control of the blood sugar during the remainder of the twenty-four hours.

Anemia in Hernia at Esophageal Hiatus—Murphy and Hay attempted to determine those symptoms which may lead one to suspect the diagnosis of hiatal hernia and to record the frequency of anemia in patients with hiatal hernia and its importance as a diagnostic aid. The data recorded are based on 72 histories of patients with hiatal hernia of whom 11 were men and 61 women. Hiatal hernia is more common in female patients. The average age was 60 years. Seven of this series had a congenitally short esophagus. Six of them were troubled with vomiting or regurgitation after ingestion of food. Substernal pain distress or a feeling of obstruction in this location was present in 5 of these patients. Obesity is an important contributory factor to hiatal hernia. Increased intra-abdominal pressure, which may be produced by excess fat in the abdomen, a large fibroid or a pregnant uterus may cause herniation. Rigler emphasized the importance of pregnancy as a factor. Slightly more than one half of this series were women who had been pregnant one or more times. Trauma is undoubtedly responsible in some cases. Pain was the symptom most frequently stressed by the patients. Anemia was present in 17 or 24 per cent of frequency. Other symptoms were less common. Gas in the stomach is usually a distressing feature. Constipation is a common accompaniment and is usually relieved by laxatives.

tory is as follows. After the ingestion of food, particularly solid or coarse, there is a feeling of obstruction or pain (ache or squeeze) in the substernal or the upper epigastric region. This may be followed by regurgitation or vomiting, with relief of symptoms. Vomiting and regurgitation of food not associated with nausea are characteristic complaints. Hiatal hernia should be more frequently included in the differential diagnosis of pathologic conditions in the upper part of the abdomen. An analysis of the blood was made in 67 of this series. A diagnosis of pernicious anemia was made in 7. In 2 other cases there was severe microcytic anemia with a high color index. If one excludes the 7 patients with pernicious anemia, there were 40, or 66 per cent, with anemia of some degree. Anemia is so commonly associated with hiatal hernia that it must be considered an important aid in the diagnosis. It is usually hypochromic and the result of hemorrhage arising from ulceration of the esophageal or of the gastric mucosa or from congestion of the mucous surfaces. Surgical intervention may be necessary in hiatal hernia, particularly when there is incarceration of the stomach in the esophageal hiatus with symptoms of obstruction and recurrence of severe hemorrhage. Medical management should include a diet low in roughage, with avoidance of solid foods; later the diet should be increased to include some moderately rough and coarse foods. It may include purged vegetables. It should be divided into five or six small meals daily. At no time should the stomach be overloaded. Loss of weight will be desirable in the obese. Patients should rest before meals. The patient should not recline soon after a meal. Those whose symptoms occur at night or on reclining will be benefited by sleeping in a semireclining position. The patient should be cautioned against lifting heavy objects or lifting any object from a bending over position. All straining and physical effort should be avoided. The hypochromic anemia should be treated with optimal doses of iron.

Local Toxic Effects of Sulfonamide Compounds—Bellows investigated the effects of local application of the sulfonamide drugs on the eyeball. The corneas of young adult rabbits were anesthetized by means of a 4 per cent cocaine hydrochloride solution, which was chosen not only for its anesthetic properties but for its drying effect on the epithelium. The drying effect was desired because it facilitated removal of the epithelium, an operation which was accomplished by immobilization of the eyeball with a fixation forceps and rubbing of the cornea with dry gauze. The cornea was stained with fluorescein to make certain that the epithelium was completely removed. Sulfanilamide, sulfathiazole, sulfapyridine and sulfadiazine were used in the form of powder, a 5 per cent ointment and a 20 per cent suspension. The drug to be tested was applied three times daily to one eye, while the other eye served as a control. These experiments yielded additional support to the contention that the sulfonamide compounds have an unfavorable effect on actively growing epithelium as shown by a greater than twofold increase in the time required for epithelial regeneration. They increase the amount of scarring. Therefore the local use of these drugs should be avoided in the treatment of injuries of the face or cornea.

Intradermal Vaccine Therapy in Brucellosis—According to Urschel intradermal injection of brucella vaccine or brucellergen causes the development of specific antibodies in the blood stream of the patient. The significance of these demonstrable antibodies in resistance to infection has not been demonstrated. In a small series of cases vaccine given by the intradermal route has given satisfactory clinical response. A mixed heat-killed stock vaccine was used. After the diagnosis has been made, treatment is begun with intradermal injections at five to seven day intervals (in an occasional case at three to five day intervals). The vaccine is injected into the forearm or into the medial surface of the thigh. Twenty intradermal injections of vaccine was the average in this group. Twenty-eight patients have received treatment by intradermal vaccine alone and three have had a combination of intradermal and subcutaneous vaccine. In 87.5 per cent of patients the intradermal administration of vaccine alone got results which were classified as fair, good or excellent. The intradermal route offers several advantages. The amount of vaccine necessary is small. The injections are relatively painless. The amount of reaction can be carefully watched and measured. Systemic reactions are few.

Succinylsulfathiazole in Chronic Brucellosis—Davis suggests that an intestinal antiseptic might solve the therapeutic problem of involvement of the digestive tract in brucellosis. Since September 1942 the author has used succinylsulfathiazole for all patients with chronic brucellosis. To date he has used this drug in the treatment of 12 patients. Six are apparently cured, 6 are much improved but under treatment, and 2 have up to the present time shown no response to the drug. The author is unable to give any explanation of the two failures.

Malaria in Iowa—Bennett reports 4 cases of malaria. The histories indicated that the onset occurred the same day. The prodromal symptoms were similar. Each patient had the initial chill, which was severe and prolonged and was followed by temperatures reaching from 104 to 105 F with subsequent sweats and weakness. The four persons had met at a picnic in a lake resort. They recalled that the mosquitoes had been plentiful. It seems possible that the inoculation occurred at this time. It is not clear where the mosquito or mosquitoes became infected. Two sources seem probable. Lake McBride is a state park and many people from a distance visit it. Some one who previously had had malaria and was a carrier might have visited there and the mosquito or mosquitoes fed on him and thus became infected. The other possible source is that in many medical centers among them the State University of Iowa Hospital, certain patients are routinely treated with malarial inoculations. A strain of *Plasmodium vivax* is used for this purpose. The same strain was detected in these patients. The treatment of malaria proved difficult. During the initial attack these patients were all treated promptly and energetically with quinacrine and quinine as soon as the diagnosis was confirmed by blood findings. During each of the following relapses they were treated with quinacrine plasmochin and quinine. Each had from three to four recurrences, all verified by finding the parasite in the blood smears.

Pain in the Fourth Metatarsophalangeal Joint (Morton's Toe)—According to McElvenny a typical case of Morton's toe is characterized by severe lancinating pain originating in the region of the fourth metatarsophalangeal joint. The pain is shooting in character and may travel up the calf as far as the knee. The pain comes on in paroxysms of varying intensity and in many subjects is accompanied by an almost uncontrollable desire of the victim to remove the shoe. The

disease occurs in men and in women in the proportion of about six to ten. This condition was first described by Morton of Philadelphia in 1876. The condition is often resistant to conservative treatment. It is caused by a tumor involving the most lateral branch of the medial plantar nerve. Careful palpation will usually reveal the tumor, which lies high in the web between the third and fourth toes. If symptoms justify it, excision of the tumor should be done. The author reports 11 cases treated by operation. Of the twelve tumors removed from 11 patients, five have had a microscopic study and appear to be either neurofibromas or angioneurofibromas. Grossly they are fatty and soft on the outside and firm, white and fibrous as the center is approached. The plantar nerve is embedded in the center.

Caffeine Withdrawal Headache—Dreisbach and Pfeiffer attempted to produce and study caffeine withdrawal headache. In a survey of 128 migraine patients 25 stated that lack of their usual coffee intake would result in headache. Five patients volunteered the information that the headache was not of the migraine type. The authors attempted to produce headache by administration of caffeine over a suitable period, usually a week, and then abruptly withdrawing the drug. In 55 per cent of thirty-eight trials on 22 subjects, headache as extreme in severity as the subjects had ever experienced was produced by the sudden withdrawal of caffeine. In 29 per cent of the trials the headache was definite but did not require treatment. In 16 per cent of the experiments little or no headache resulted. The headache is without scotomas, slow in onset and central in origin, becoming generalized after four to six hours, it may be accompanied by nausea and vomiting. In migraine subjects the headache differs from their typical migraine headache. The blood studies indicate that a lowered serum calcium, an elevated serum phosphorus and possibly an increase in blood volume accompany the headache.

- War Wounds of Abdomen. D. L. Borden—p. 213
- Practical Problems in Blood Grouping and Blood Transfusion. R. F. Peterson—p. 215

Rocky Mountain Spotted Fever—Baker points out the close resemblance of endemic typhus to Rocky Mountain spotted (tick) fever. The degree of protection afforded by vaccine and the duration of such protection vary. As a rule those vaccinated in the spring of the year retain a considerable degree of immunity for at least the remainder of that year. Treatment of tick fever is purely symptomatic and supportive in character.

Bed rest with good nursing care is necessary. The author had occasion to study the various aspects of tick fever in a section of Wyoming where the disease occurs with considerable frequency. In 1934 Kamp and the writer received encouraging reports of responses obtained in typhus by use of neoarsphenamine dissolved in aqueous solution of metaphen. In the spring and summer of 1934 they used this treatment in 9 moderately severe cases of the disease. None of the patients succumbed to their illness. Since that time an average of 3 to 4 cases of tick fever have been under the writer's care each season. During the past eight years recovery has occurred in all cases so treated. A combination of the bactericidal action of metaphen, together with the spirocheticidal action of neoarsphenamine, on a micro-organism which is bacterium-like in character yet has staining properties similar to those displayed by spirochetes may be the secret of the success. In this treatment 0.3 Gm of neoarsphenamine was dissolved in 10 cc of an aqueous solution of 1,000 metaphen. The mixture was warmed and injected slowly into a vein. Administration is repeated at three or four day intervals. Three or four injections have customarily been sufficient to ameliorate the clinical picture so as to insure ultimate recovery. Should severe renal injury exist as a result of the infection, careful consideration must then be given the question as to whether the use of these medicaments is justified.

Vitamins in Meat During Storage, Curing and Cooking—For the experiments carried out by Schweigert and his associates pork hams were taken from carcasses weighing approximately 190 pounds. Paired hams were used throughout the experiment. Two fresh hams were analyzed immediately and the two corresponding hams were stored for fourteen days in a freezer (−4 C) in order to determine the vitamin retention during storage. Two different hams were stored for fourteen days and the corresponding two hams were cured commercially in order to study vitamin retention during the curing process. Four additional hams were cured. Two of these were analyzed uncooked and the two corresponding hams were used for cooking tests. The authors found that average retention during storage is 92 per cent for the thiamine and nicotinic acid and 85 per cent for the riboflavin. The retention in curing was found to be 73 per cent for the thiamine, 84 per cent for the nicotinic acid and 92 per cent for the riboflavin. The average retention in the meat alone after roasting was 58 per cent for thiamine, 79 per cent for the nicotinic acid and 74 per cent for the riboflavin, after frying, 86 per cent for the thiamine, 85 per cent for the nicotinic acid and 77 per cent for the riboflavin. The average total retention in the meat plus drippings after roasting was 70 per cent for thiamine, 96 per cent for the nicotinic acid and 84 per cent for the riboflavin after frying, 92 per cent for the thiamine, 96 per cent for the nicotinic acid and 86 per cent for the riboflavin. The overall retention of the vitamins from fresh stored to cured and cooked samples agrees very well with the vitamin retention during curing and frying. From 10 to 15 per cent of each of the vitamins was found in the drippings from roasting and frying. A higher retention of thiamine in the meat alone was noted after frying, as compared with roasting, braising and broiling.

Effect of Cholesterol Administration on Anesthesia—Foldes and Beecher were able to confirm for ether and a barbiturate the principal conclusion of Starkenstein and Weden that the depth and duration of anesthesia can be greatly increased by the previous injection of cholesterol. The cholesterol effect appears to be a potentiation the possibility that it may be additive cannot be eliminated at this time. In searching for an explanation of the cholesterol action one must look beyond physical solubility and transport effects. (a) Both olive oil and cholesterol increase the effectiveness of ether, but only cholesterol increases the effectiveness of the barbiturate. Olive oil has no effect on the barbiturate. (b) Ether has the same order of solubility in both cholesterol and lecithin yet cholesterol increases the anesthetic effect of ether (and barbiturate) while lecithin does not.

Thiouracil in Treatment of Thyrotoxicosis—Recently substances have been described which induce goiter presumably by their direct action on the thyroid. Such substances are the sulfonamides thiourea and thiourea derivatives. Following their administration to certain animals particularly rats, thyroid enlargement results in a few days. Microscopically one finds hyperplasia of the acinar cells and a decrease in the colloid of the follicles. A drop in the basal metabolic rate occurs. These changes can be prevented by the administration of desiccated thyroid or thyroxine. They can also be prevented by hypophysectomy but not by the administration of iodine. In rats fed sulguandine changes in the pituitary glands similar to those following thyroidectomy take place. These facts suggest that the drugs act directly on the thyroid gland inhibiting the

production of thyroxine thus in turn leading to a decrease in the body metabolism and to an increased activity of the pituitary gland. The authors have been studying some of the pharmacologic and therapeutic effects of thiouracil in patients with thyrotoxicosis. None of the patients were given iodine. Thiouracil was given by mouth usually in doses of 0.2 Gm. The authors give detailed histories of 9 unselected patients with thyrotoxicosis whom they treated with thiouracil. In each case the toxic manifestations disappeared and the basal metabolic rate returned to a normal range. Blood iodine studies conducted on 4 patients showed in each a fall of the protein bound iodine to a low normal or subnormal level. Studies have been performed of the blood levels of thiouracil and its excretion in the urine. No serious complications from the drug have been encountered, but all patients receiving the drug should be carefully followed. This report deals only with the early changes resulting from the treatment with thiouracil.

Diaphragmatic (Hiatus) Hernia—Ohler and Ritvo collected from the records of the Boston City Hospital 128 cases of diaphragmatic (hiatus) hernia during a period of less than four years. They conclude that the condition is not rare. The symptoms are such as to justify its inclusion in the differential diagnosis of anterior chest or upper abdominal complaints or both. The typical symptom of hiatus hernia is a sense of epigastric pain, distress and fullness coming on shortly after or during meals. Often there is difficulty in swallowing solid food. Frequently there is epigastric pain or distress at night or when the patient is in the recumbent position. In most cases the pain is relieved when the patient assumes the upright position. There may be substernal pain or dyspnea or both—generally but not always unrelated to exertion. The pain may present radiation similar to that of angina pectoris, but just as frequently its radiation is atypical. The patient with hiatus hernia may bleed. The bleeding may explain the anemia characteristic of chronic blood loss. The x-ray examination should always begin with fluoroscopic observations without the opaque meal. A careful search is made for a gas containing shadow lying at or slightly above the level of the diaphragm. This is of particular importance, since in some cases the hernia reduces itself and disappears on ingestion of the opaque meal. Observations are first made with the patient breathing quietly, then in full inspiration and forced expiration. The frontal and oblique positions are used in the erect prone and supine positions. When the opaque meal is administered the fluoroscopic observations are best begun with the patient in the erect position. The great majority of hernias are not demonstrable in this position. The lesion will not be visualized if the x-ray observations are carried out only with the patient upright. Treatment is essentially medical especially in patients with small lesions. A bland high vitamin diet divided into four or six feedings is desirable. Food should not be given before bedtime. Assumption of the upright position after eating or for a few minutes during the course of the meal is often helpful. Sleeping at an angle of 45 degrees has relieved distressing night symptoms. Alkaline and antispasmodic drugs are frequently useful. Surgery is indicated when medical measures fail especially for patients having intractable pain or hemorrhagic tendencies.

Rocky Mountain Spotted Fever—Sizemore reports observations in 7 cases of Rocky Mountain spotted fever. The cases occurred in a family in the town of Armstrong in Bryan County, which is located in the south central section of Oklahoma. The family lived here for several years but had moved into a new, unpainted, green lumber house only a short distance from their previous home. The household consisted of a couple, their 3 children and the wife's mother. The latter, aged 67, died of the illness contracted by all of them. All developed what was first suspected to be typhus but later was identified as Rocky Mountain spotted fever. The attending physician, Dr. Flythe, aged 44, died of the disease. A man aged 47 who had

stayed at the home of the family while the first 3 members were ill became ill and died. The rash suggested that this fatality was also caused by the Rocky Mountain spotted fever. Questioning brought out the fact that all members of the household had been bitten repeatedly since moving to the new house by ticks which infested the yard. The gopher proved to be the ticks' host in the Armstrong area. The use of vaccine in infested areas each year is indicated. This is best given in late winter or early spring. The vaccination should be completed at least ten days before the first expected exposure. The vaccine is not recommended for therapeutic use.

Inadequate Surgery in Carcinoma of Cervix—According to Scheffey and Hahn surgical measures of an ill advised or inadequate nature are being employed too frequently in carcinoma of the uterine cervix. They criticize operative management of this sort and emphasize the contraindications and technical limitations. Radical surgery for carcinoma of the cervix is a recognized method of treatment only on the condition that such a patient has been carefully selected. The lesion must be a relatively early one (groups I and II, Schmitz and League of Nations), the patient should be a reasonably good surgical risk and a radical operation must be performed by an operator thoroughly experienced in its exacting technique. The authors review results observed on 18 patients subjected to operation in whom recurrence was relatively prompt. Two groups consisting of 9 patients each were seen at the Jefferson and Oncologic hospitals of Philadelphia respectively. It is evident from the histories that in each instance either an inadequate operation was performed or proper indications for such an operation were lacking. The short survival of the patients subjected to vaginal hysterectomy is especially appalling when one considers that they were young women with supposedly operable lesions. The surgical procedure was probably not of the type of which Lynch, Bonney and others of similar experience are capable. If the decision to operate is made, it must be a selective operation not only carried out by one qualified to perform a truly radical operation but based on the premise that the lesion is undoubtedly early, that the patient is an excellent risk and that intracavitary irradiation with radium has been a preliminary procedure. The authors feel that carcinoma of the uterine cervix is best treated with radiation therapy alone. There may be certain patients, carefully selected, who might possibly have a better chance for longer survival when treated surgically by one experienced in the rigorous technique of the radical operation, preceded by irradiation, but in general this is not so. Hence it would be wiser to avoid surgery in the treatment of cervical carcinoma, for a simple type of vaginal hysterectomy or abdominal panhysterectomy is at best only a hazardous and delaying measure in such instances.

Carcinoma of Cervix—According to Johnston cancer of the cervix causes about 15,000 deaths each year in the United States, more deaths than any other gynecologic disease. The author reviews 233 cases of cervical cancer that were registered at the Tumor Clinic of the West Penn Hospital during the last ten years. Twenty-nine per cent occurred in women under 40 years of age. Patients present themselves too late for a

ment, as more than 50 per cent had symptoms for six months or longer. The diagnosis of cancer of the cervix is made by careful inspection and palpation of the cervix and by biopsy. At times, when no lesion is visible, a cancer can be detected by palpation, the hypertrophied indurated cervix indicating a carcinoma which can be proved by curetting the cervical canal. Biopsies should be made on all suspected lesions. Up to 1937 most of the cases were treated with radium followed by x-rays. Of late x-rays have been followed by radium. The x-ray dosage varies with the tolerance of the patient, usually from 1,600 to 2,200 roentgens to each of four ports over a period of three weeks. The radium is given in doses of 3,600 to 4,800 mg. hours. Some have had interstitial radiation in the form of four or five 10 mg. needles inserted in the parametrium. Treatment is not repeated unless there is a recurrence as proved by biopsy. The possibility of fistulas and rectal ulcers due to radiation reaction should be remembered and precautions taken to avoid them. The results in 103 five year cases show a survival rate of 33.9 per cent.

Perineal Prostatectomy versus Transurethral Resection—Young analyzed the histories of all patients (now totaling 200) who have come to the Brady Urological Institute complaining of imperfect results following transurethral resection elsewhere. He concludes that in patients with considerably enlarged prostates complete enucleation of the hypertrophied lobes through the perineum gives better results and is no more dangerous than transurethral resection. Prostatitis and painful urination are certainly less common after perineal prostatectomy than after transurethral resection. Another great advantage of the perineal procedure is the opportunity which it affords to make a diagnosis and effect a cure of carcinoma of the prostate. Many conditions, particularly bars, contractures and small hypertrophies can be dealt with efficiently by transurethral resection, but perineal prostatectomy is distinctly superior for the larger hypertrophies, calculi in the prostate and chronic prostatitis. Prostatism is so complex in its symptoms and so varied in pathologic aspect that it can be handled satisfactorily only by careful selection of the operative procedure best suited to obtain a radical cure. The exclusive use of transurethral resection for all types of prostatic obstruction, even the large and the cancerous is indefensible.

Visceral Lesions Associated with Rheumatoid Arthritis—Fingerman and Andrus examined the records of 192 cases with a diagnosis of arthritis. There were 61 cases of rheumatoid arthritis. The authors apply the term rheumatoid to the severe deforming type of chronic infectious arthritis. The criteria used in selecting these cases of rheumatoid arthritis were as follows: The disease must have been chronic, being present a minimum of several months. It must involve two or more joints. It must have caused deformities of the joints and their adjacent structures. It must be of a nonsuppurative type. The authors examined the clinical records and available pathologic material from 61 patients who had died with chronic rheumatoid arthritis. Lesions indistinguishable from those found in the rheumatic heart were encountered in 19 cases (31 per cent). Six of the patients with rheumatic heart lesions had congestive heart failure as evidenced by chronic passive congestion of the liver. Only 3 persons in the entire group had "Felty's syndrome," or chronic arthritis associated with splenomegaly and leukopenia. There were 6 other patients with splenomegaly along with the arthritis deformans who did not have leukopenia. Amyloidosis involving one or several organs was found in 13 patients (21 per cent). Glomerulitis was found in 8, of which 6 were in early subclinical stages, and the remaining 2 had clinical evidences of glomerulitis.

Sulfonamide Compounds in Intestinal Infections—Clay reviews 273 cases of bacillary dysentery treated at the City Hospital of Aberdeen during 1941 and 1942, 4 cases of gastroenteritis in infants and 8 cases of paratyphoid B. Of the patients with bacillary dysentery 140 received no drug, 83 were treated with sulfaguanidine, and 50 received sulfanilamide. Adults not receiving chemotherapy were given 2 drachms (8 Gm) of sodium sulfate night and morning and children 1 drachm (4 Gm) night and morning. Those receiving sulfaguanidine were given a five day course based on body weight, the initial loading dose during the first twenty-four hours being 0.5 Gm per kilogram of body weight, followed by a maintenance dose of 0.1 Gm per kilogram for the next four days. Those receiving sulfanilamide were given a dosage amounting to half the quantity of sulfaguanidine. The tablets were powdered and administered in milk every four hours for the first twenty-four hours and three times daily for about the next four days. Fluids were given intravenously in the form of 5 per cent dextrose in isotonic solution of sodium chloride when necessary, and particular stress was laid on fluid intake by mouth, 8 to 10 pints for adults and proportionately less for children. The stay in the hospital and the number of days during which the stools remained positive were reduced by half for patients receiving

sulfaguanidine as compared with those not receiving chemotherapy except in the case of Sonne convalescent carriers, whose stay in the hospital and number of days bacteriologically positive were slightly increased. Of the patients receiving sulfanilamide both the stay in the hospital and the length of time during which stools remained positive were increased, but this may be accounted for by the small dosage of drug and by the small number of patients treated. Neither sulfaguanidine nor sulfanilamide produced toxic symptoms or disagreeable effects. Four patients with gastroenteritis and 8 with paratyphoid B were treated with sulfaguanidine without improvement.

Desoxycorticosterone in True Adrenocortical Insufficiency—Heni investigated the cause of edema and hypertension in the course of treatment with desoxycorticosterone acetate. He describes observations on healthy subjects and on patients which convinced him that the chief action of desoxycorticosterone acetate is that on the sodium chloride and water economies. Sodium and water are retained in the blood and extracellular spaces and cause increase in blood pressure. If large doses of desoxycorticosterone acetate are used, edema may result. Edema, hypertension and acute shock are not caused by excessive intake of sodium chloride but by desoxycorticosterone acetate. The effect of this substance on the potassium exchange is not as noticeable as that on the sodium. The carbohydrate metabolism is not completely normalized and the fatigability of the patients is not counteracted when signs of excessive dosage appear already in the sodium chloride exchange. Desoxycorticosterone acetate in doses as large as possible was given to 4 patients with Addison's disease. It was impossible to obtain complete restoration in spite of prolonged medication. The patients still felt weak. Complete recovery was obtained only in those whose disease was moderately severe. The authors conclude that although desoxycorticosterone acetate is the best available remedy for Addison's disease their observations indicate that desoxycorticosterone acetate or desoxycorticosterone either are not identical with the adrenocortical hormone or do not represent the only hormone of this organ. Substances chemically related to desoxycorticosterone are capable of exerting favorable effects on the metabolic disturbances of Addison's disease. In severe forms of the disease only progesterone is effective, in mild forms testosterone and low doses of estrone (theelin) effect improvement. These substances do not act by way of the sodium chloride and water exchange, but they improve the glycogen reserve of the organism, particularly that of the musculature. Progesterone might be used in the treatment of severe Addison's disease if moderate doses of desoxycorticosterone cause disturbances in the sodium chloride and water economies.

New Hereditary Agglutinable Factor in Human Erythrocytes—A new hereditary agglutinable factor could be detected in human erythrocytes by guinea pig immune serum produced with blood of rhesus monkeys. In 923 out of 1,129 blood tests, or in 81.5 per cent, the agglutinin which had been designated as Rh was found, whereas in 206 blood tests or 18.5 per cent, it was not found. The distribution among the ABO blood groups, the A subgroups and the MNP type seemed to be equal. Studies of 46 pairs of twins suggest that the agglutinin Rh is hereditary. Results of study in a number of 17 families are compatible with the assumption that agglutinin Rh is a simple dominant inherited character.

Convulsive Seizures How to Deal with Them a Manual for Patients Their Families and Friends By Tracy J. Putnam M.D. Professor of Neurology and Neurosurgery College of Physicians and Surgeons Columbia University New York Cloth Price \$2.00 Pp 168 with 12 illustrations Philadelphia Montreal & London J. B. Lippincott Company 1943

There is a real need for a book to which the victims of convulsions and their families can turn for reliable information. In a large measure this book supplies that need. The task of any book which would instruct patients is a difficult one. Such a book must on the one hand be accurate and sufficiently complete to supply the patient with the required information without at the same time frightening him with rare and unlikely complications of his disorder and without providing just enough information to encourage self medication. A book which would treat of "epilepsy" has one other requirement which it must meet—it must help to brush away the superstitions, fears and inaccurate concepts which have grown up about the convulsive states of unknown origin. If the present book has any one general failing it is that it is not sufficiently forceful on the latter point. It says but it does not sufficiently stress the facts that in the majority of cases the convulsive seizures can be completely abolished if adequate treatment is begun early and persevered in and that such patients need have no fear of insanity or mental deterioration and can and should lead perfectly normal healthy lives with the same chances to achieve happiness and success in their chosen occupation as other people. The author tends far too much to view 'epileptics' as a group, making no effort to separate the mentally retarded with convulsions and those with uncontrollable seizures from the larger and far more favorable group. It is these less fortunate individuals, in particular, that bring down the average of physical fitness noted on page 23.

The author has also been too much impressed with some rather poorly considered statistics on the inheritance of convulsions or a convulsive tendency (pp 22 and 119). In these statistics, as he noted himself, the rather uncommon instances of definitely hereditary epilepsy were not separated from the far more common sporadic cases. Likewise he has been overly impressed with the value of electroencephalography in selecting individuals with or without the probable potentiality of perhaps producing epileptic children (see p 151). Not all of those with experience with electroencephalography would agree that the technic has any such capabilities.

Chapter 8, on medical literature, and chapter 9, on the legal aspects of epilepsy, had best be omitted from this book. The latter chapter could well be enlarged for publication in some journal for lawyers or for presentation before legislators. It detracts from the value of this book.

The author is to be complimented for having avoided fads and all peculiar forms of treatment which have found favor in only a few hands. The reviewer's experience would lead him to feel that the restrictions on alcoholic beverages for these patients should be complete and not as lenient as those given here (p 92).

This book can be recommended to some patients and to more families. No doctor should recommend it without first reading it. It should be placed only in the hands of intelligent and fairly stable people. It is not a book for the overapprehensive worrisome, easily agitated person. Such people would find more than enough to exercise them here.

A Handbook for Emergency Commissioned Officers of the Indian Medical Service By Lieut Colonel I. R. Dogra M.D. M.S. Foreword by Major General J. N. Thomson D.S.O. M.C. Boards Pp 202 Bombay Thacker & Co. Ltd. 1943

This handbook contains the essential information required to orient completely the emergency commissioned officer of the Indian Medical Service. In addition the book contains basic reference material which the officer will want to refer to until he becomes thoroughly acquainted with it. Any army medical department officer would find this handbook distinctly helpful if he should be destined for service in India or with the Indian army.

It will require four to five hours of careful reading to digest the 136 pages of subject matter. Appendix VII, appendix VIII and appendix IX should be studied carefully first. This procedure will eliminate too frequent reference to the appendix and permit continuous reading. By the use of many abbreviations many facts have been transmitted in comparatively few pages. It is hard to believe that this small handbook can and does include all of the following essentials: organization of the army in India, the medical officer and his relationship to the army, military life, military dress, military courtesy, military discipline, military law, organization, functions and operation of the medical units, duties of medical officers in their various capacities in field and garrison service, field sanitation and preventive medicine, collection and evacuation of casualties, preparation of orders, messages, estimates of the medical situation and medical forms, and, in addition, six appendices, which include translation of the Geneva Convention, uniform and equipment for emergency commissioned officers, lecture demonstrations, medical standing operative procedures, water sterilization, army forms required by the medical service, medicomilitary definitions and abbreviations.

The medical department officer of the United States Army who reads this book should review our own medical service procedure and installations before he reads it. More enjoyment will be gained thereby in the comparison. For example, he should be able to associate quickly such medical installations as the regimental aid post, advanced dressing station, main dressing station and casualty clearing station with respective stations of our service. He will then be able to trace the casualty through the echelons of evacuation as operated by the Indian Medical Service.

This book reveals a vast amount of experience on the part of the author, who has presented ideal and essential information in a condensed form. It is highly recommended to every Medical Department officer who has interest in medical service of another army or who might serve with the Indian Medical Service.

The Determination of Blood Groups Medical Research Council War Memorandum No 9 Paper Price 10 cents 4d Pp 19 New York British Information Services London His Majesty's Stationery Office 1943

The experience gained from the large scale blood group determinations in Britain during the last three years has suggested "that certain procedures, rigidly followed will reduce errors in grouping to a minimum." To that end the memorandum was compiled by members of the Blood Transfusion Research Committee appointed by the Medical Research Council. Tests for ABO blood groups subgroups of A, crossmatching tests, preparation and storage of test serums sources of error and the Rh factor are presented. The completeness of information offered in the sixteen pages of text, the excellent selection of the recommended methods and the emphasis on sources of error combine to make this pamphlet a most valuable contribution to be placed in the hands of clinical pathologists and of technicians who do pretransfusion tests. It can be recommended as the best of its size.

Essentials of Proctology By Harry E. Bacon B.S. M.D. F.A.C.S. Professor and Head of the Department of Proctology Temple University Medical School and Hospital Philadelphia Introduction by Curtice Rosser B.A. M.D. F.A.C.S. Professor of Proctology Baylor University Dallas Cloth Price \$3.50 Pp 345 with 185 illustrations Philadelphia Montreal & London J. B. Lippincott Company 1944

The author has taken from his own earlier work portions of those chapters which deal with practical phases of proctology and problems of interest to the physician as he goes about his daily tasks. It is a convenient little volume which should prove valuable to those who do not possess the author's more complete volume. In the foreword Dr Curtice Rosser wrote: "In The Essentials of Proctology which Dr Bacon here offers to the student the general practitioner the surgeon and the specialist in colorectal diseases is a concise fluent and detailed exposition of the author's own experience and current practice. This is an accurate appraisal of the character of the book."

INQUIRIES COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

UNCONSCIOUSNESS AT HIGH ALTITUDE AND OXYGEN SUPPLY

To the Editor—In *The Journal*, July 24, 1943, there is an article on a parachute jump made by Lieut. Col. William Lovelace from 40,000 feet. The statement was made in the third paragraph that unconsciousness occurred within fifteen seconds without oxygen at 40,000 feet. Since many people can hold their breath for a much longer period of time and even swim under water for longer than fifteen seconds I was wondering whether or not this was a typographic error or whether there were other factors.

Raul Pietri, M.D., Asbury Park, N. J.

ANSWER—Unconsciousness occurs within fifteen seconds without oxygen at 40,000 feet if the person continues breathing. Once a man is disconnected from his oxygen supply his first expiration empties his lungs and inspiration thereafter takes in air which is so deficient in oxygen that unconsciousness will ensue almost immediately. The actual saturation of blood at 40,000 feet, breathing pure oxygen, is slightly less than normal, consequently the decline in saturation or onset of unconsciousness occurs with extreme suddenness. This is inherent in the nature of the saturation curve of hemoglobin. If a man at 40,000 feet takes a deep breath and holds it, he will remain in much better condition than if he continues breathing after disconnecting his oxygen supply. It might be further stated that the actual oxygen consumption at 40,000 feet is approximately the same as at ground level or at 300 cc standard temperature and pressure dry per minute. The actual volume of oxygen in the lungs is approximately 1,000 cc standard temperature and pressure dry per minute when breathing pure oxygen at 40,000 feet. From this it readily can be seen that the interval of reserve is extremely small even when one is holding the breath.

APLASTIC ANEMIA AFTER EXPOSURE TO FLOOR WAX AND FLY SPRAY

To the Editor—Can you inform me of the ingredients of Veeco Self-Polishing Wax, manufactured by the American Products Company of Cincinnati and of Wax Rite Floor Wax, manufactured by the Vestal Chemical Company of St. Louis? A 3 year old child was found to be suffering from a profound anemia and leukopenia. Bone marrow aspiration revealed an aplastic type of marrow. A history of exposure to these waxes was obtained, and it was also learned that the child had been exposed to fly spray used in a dairy barn. Are there any ingredients used in the more common fly sprays which are known to be toxic to the hemopoietic system?

John W. O'Neill, M.D., Eau Claire, Wis.

ANSWER—The two floor waxes mentioned by name are believed to be of the aqueous soap emulsion type and therefore contain only water as the solvent and none of the organic solvents widely common in some other varieties of floor waxes. Apart from certain hydrocarbon solvents later specified, floor wax ingredients do not cause the clinical manifestations mentioned in the query, although some may induce dermatitis. The organic solvents most likely to appear in floor waxes are toluene, trichloroethylene, naphtha, alcohols and petroleum ether. If benzene or carbon tetrachloride should be utilized potentially, highly dangerous situations might arise. Benzene is known to induce the symptoms described. If any of the floor waxes now questioned has been retained, analyses should be made for benzene although in both instances there is assurance from the manufacturer that no solvent other than water enters the formula. A typical formula for a floor wax of the non-soap emulsion type is East India gum 23 pounds, beeswax 6 pounds, Carnauba wax 20 pounds, Montan wax 8 pounds, naphtha 89 pounds, turpentine 10 pounds, pine oil 3 pounds. Pyrethrum is scarce in this country just now, earlier having chiefly been obtained from Japan. Some insecticides formerly containing pyrethrum as the main insecticidal agent no longer contain it. If, in fact, a pyrethrum spray was used, and this was a well known brand, some petroleum derivative such as naphtha was probably the extracting agent. However, almost any agent might have been employed under present conditions, including dichloroethylene, carbon tetrachloride, trichloroethylene and conceivably benzene. Since exposure probably was limited to a few short periods, this etiologic possibility seems remote.

HYPERSENSITIVITY TO SULFONAMIDES

To the Editor—Has any work been done to determine how long sensitivity to sulfonamides is maintained and the amount necessary to cause exacerbation? Is it possible to desensitize an individual who is sensitive?

M.D., Massachusetts

ANSWER—It is not known from any extensive study how long a patient remains sensitive to sulfonamides. However, isolated cases are on record in which sensitivity was shown to persist for as long as three years. The amount of sulfonamide necessary to cause an exacerbation is usually small, so that a single dose of 0.6 Gm. may cause symptoms in a sensitive person. There are no good methods available for desensitizing patients. Sensitization to the sulfonamides is usually but not always specific. That is to say, there is usually no cross sensitization. If a patient is sensitive to one sulfonamide compound, another compound can usually be given with safety.

VITAMIN B COMPLEX AND TINNITUS

To the Editor—What do you feel would be the proper dose of vitamin B₁ for a tinnitus, which ear, nose and throat specialists say has no apparent cause other than possible nerve involvement? There is no deafness.

M.D., New York

ANSWER—There is no satisfactory evidence that vitamin B₁ (thiamine hydrochloride) is of any help in cases of tinnitus or nerve deafness. Since vitamin deficiencies are generally multiple, it would seem wise to give the whole vitamin B complex rather than just the B₁ fraction.

An article by Shambaugh and Jennes in the *Archives of Otolaryngology* (35:513 [April] 1942) summarizes the literature on vitamin B in deafness and gives the results of use of large doses of B₁ in cases of tinnitus in deafness, which were entirely negative.

BARBITURATES WITH SCOPOLAMINE IN OBSTETRICS

To the Editor—Can you give me information on the use of barbiturates combined with scopolamine for obstetric analgesia? I should like to know the dosage and how soon it could be repeated. Also is it free from the objections that "twilight sleep" has, that is, I suppose it was the morphine part of twilight sleep that was dangerous to the baby rather than scopolamine, wasn't it? Will you please set me straight on this.

George A. Bakke, M.D., Oakland, Calif.

ANSWER—The barbiturates can be used in conjunction with scopolamine to provide obstetric analgesia. Their effectiveness depends on the drug selected and the amount administered. Unlike morphine, which is primarily an analgesic drug, the barbiturates induce amnesia rather than analgesia. Large amounts are usually necessary to provide desirable effects during labor. The barbiturates, like the opiates, produce narcosis in the newborn. Effective doses will result in asphyxia, which is just as severe as that induced by morphine, or even more severe. An initial dose of such barbiturates as secobarbital or soluble pentobarbital in combination with scopolamine may be 3 to 6 grains (0.2 to 0.4 Gm.). The barbiturate may have to be repeated in four to six hours to maintain the desired effect. Larger doses have been advocated, but these are not desirable in most instances. Patients in labor under the effect of barbiturates must be constantly attended, for their semiconscious, often delirious, state may lead to unpleasant and serious complications.

MALARIA IN ALABAMA

To the Editor—The answer to the query of "M.D., Florida" about malaria in southern Alabama, and particularly a "gulf town in Alabama" which appeared on page 1152 of *The Journal*, Aug. 14, 1943, would not lead an uninformed person to a proper conclusion. The reply errs in stating that "chances of contracting the disease by unacclimated persons would be great." To take a considerable and representative population such as that of Mobile County as a basis of measurement, the vast majority of persons never in their lifetimes have either acute or chronic malaria. If the infection rate is a hundred times as high as the death rate, which for the county varies between 0 and 9 per hundred thousand, the morbidity per year is only between 0 and 0.9 per cent. Those would not be all new cases, of course, but a total including reinfections and infections carried over. The significance of that last point is great because the disease is focalized more than the statement would lead one to believe. Where residence is even moderately dense, *Anopheles quadrimaculatus* breeding has been mainly controlled, if it ever occurred, or, conversely, where breeding of this mosquito could not be controlled, residence has not become or remained dense. As an example, in the entire Mobile metropolitan or "defense" area last year so few *A. quadrimaculatus* mosquitoes could be found either in breeding areas or in adult catching stations that there was a repeated threat that all financial aid for survey and control activities would be withdrawn.

It is true that military forces and, in years past but probably not recently, industries have selected sites unfortunately without consideration of conditions which might affect malaria transmission. These, as well as individuals and families, could have settled in the same general area, or perhaps on sites only a mile or two away with a high degree of safety.

GASTROINTESTINAL DISTURBANCES IN THE COMBAT AREA

I. PRELIMINARY OBSERVATIONS ON PEPTIC ULCER

CAPTAIN ALEXANDER RUSH
MEDICAL CORPS, ARMY OF THE UNITED STATES

The basis for this report is the fruit of a year's experience in a large hospital in the South Pacific close to the zone of combat. The findings reported are the result of the study of 200 consecutive patients admitted to the medical service because of gastrointestinal disorders. This figure represents 6 per cent of the total number of medical admissions during the year. This percentage appears disproportionately low when compared with the experience of other institutions.¹ However, it does not include patients admitted because of either dysentery or jaundice.

In civilian practice it is seldom imperative to make an immediate diagnosis in dealing with a patient experiencing the symptoms of peptic ulcer. Especially when the diagnosis is not clear, supportive dietary measures may be sufficient to keep the patient at his job. In military practice the converse is true. Since a satisfactory dietary regimen is not possible while the patient is on active field duty and since the only other alternative—extended hospitalization—impairs the military efficiency of the soldier's unit, an early diagnosis is demanded. The soldier must be promptly and definitely declared either fit or unfit for active duty. Only on the basis of such information can unit commanders keep their organizations at peak strength and efficiency. Thus peptic ulcer in the field presents new ramifications to an old problem.

INCIDENCE OF PEPTIC ULCER

Peptic ulcer was diagnosed in slightly over 10 per cent of all medical patients admitted during a twelve month period beginning in March 1942. This figure represents approximately 19 per cent of patients admitted to the wards for treatment of disorders of the upper gastrointestinal tract. Of the figures on hand at this writing, only those of the New Zealand forces in the Middle East compare favorably with these. They report the presence of peptic ulcer in 18 per cent of 100 patients admitted because of dyspepsia.² Allison and Thomas³ reviewed 100 cases of dyspepsia among sailors and marines and gave 45 per cent as the figure for the incidence of peptic ulcer. Likewise Chamberlin and Berk described peptic ulcer as occurring in 31 per

cent and 41 per cent of those admitted to the gastrointestinal services of the Lawson and Tilton general hospitals respectively.¹ The explanation for these differences is not clear. However, the disparity may be related to the locality and the type of hospital from which the latter reports emanate. Both the New Zealanders and ourselves were drawing patients directly from the combat troops in the field. On the other hand, the large general hospitals frequently obtain the majority of their patients by transfer from other smaller installations. The latter have screened out the run of the mill medical patients and transferred the soldiers with serious incapacitating illnesses, such as peptic ulcer, to the general hospitals. Under these circumstances it can be seen that the incidence of certain diseases would appear higher in the clinical material of army general hospitals than in that of field hospitals.

CLINICAL HISTORY

Approximately half of our patients with ulcer gave clearcut histories of previous attacks. This observation lends little support to the contention that army rations or living conditions in the field bear any direct relation to the production of peptic ulcer. A typical and classic history was obtained from 80 per cent of the patients with ulcer. There is no question that a careful chronological compilation of symptoms is of inestimable value in reaching a satisfactory diagnosis. However, soldiers soon learn that a certain set of complaints is commonly associated with peptic ulcer and that this disease is one for which they will be sent home. Consequently a classic history in the absence of corroborative evidence must be looked on with suspicion. On the other hand, the dictum that "the stomach is the greatest liar in the body" has been found to be equally true. Disconcertingly often a soldier who gave a history typical of irritable or spastic colon was shown by x-ray examination to have undeniable evidence of peptic ulcer. The gastrointestinal disturbance of 10 per cent of the patients with peptic ulcer was thus misdiagnosed as functional. In regard to another 10 per cent a similar misdiagnosis was made but with the added note "ulcer to be ruled out." This makes a total of 20 per cent wrong diagnoses based solely on the history. The two extremes described emphasize the importance of viewing the patient as a whole and of drawing on every available means of diagnosis. Reliance on a single symptom, sign or examination is likely to lead to serious errors.

EXAMINATIONS

Physical Examination—Sixty per cent of the patients with ulcer had tenderness in the epigastrium. In one fourth of these the tenderness was unmistakable. No relation, however, could be established between the type and locality of the lesion and the character of the pain and tenderness.

X-Ray Examination—Sixty-seven per cent of the diagnoses of peptic ulcer were supported by x-ray evi-

PROPERTY OF THE
JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

dence. A crater was demonstrated in only 21 per cent of the patients with positive x-ray signs. This figure differs widely from those of some of the better known gastroenterologic services in large civilian hospitals, where direct x-ray evidence is said to be obtainable in approximately 95 per cent of the patients with ulcer.⁴ Two factors may be responsible for this difference. In the first place the technical difficulties in the field have been great and mucosal relief studies have been out of the question with the equipment at hand. In the second place it is possible that an unusual state of affairs exists among military personnel on active duty, which may influence the roentgenologic demonstration of peptic ulcer.

This is illustrated by the following comparison. In civilian practice there is commonly a delay between the onset of the symptoms of ulcer and the x-ray examination. The first symptoms are seldom incapacitating, and the patient finds sufficient relief by eating between meals and by consuming quantities of alkali. Finally, after a period of time or after several bouts of distress increasing in severity, these simple measures are no longer effective. It is only then, some time after the first appearance of symptoms, that the patient comes before the physician and eventually the fluoroscopic screen. By this time the pathologic process may have had ample opportunity to proceed unhampered to the point where x-ray demonstration is relatively simple. In contrast, the soldier in most instances is required to perform hard physical work under conditions such that he is unable to obtain either food or medication between his regular meals. For this reason he probably seeks medical relief sooner than the majority of civilians. At this early date the chances of demonstrating a small lesion by the techniques available in the field are probably extremely poor. Thus it is felt that too much reliance cannot be placed on a negative x-ray report in the field.

Gastric Analysis—A fractional gastric analysis using alcohol, histamine or intravenously injected insulin as the stimulus was performed on every patient admitted to the gastrointestinal section. In no instance did a fractional gastric analysis contribute directly to a positive diagnosis of peptic ulcer. It is true, however, that a peptic ulcer was never found to occur in a patient who had no free hydrochloric acid in his gastric secretion. Furthermore, fasting gastric contents that were repeatedly high in free acid and of a volume greater than 150 cc invariably were associated with other definite evidence of peptic ulcer.

For the foregoing reason and because of the tremendous amount of time involved, the routine use of fractional gastric analysis was discarded in favor of examining the fasting contents alone. Should no free acid be demonstrated in the gastric juice on adding a few drops of Topfer's reagent, a suitable stimulus was given such as subcutaneously injected histamine or intravenously injected insulin. At one hour and at one hour and a half after the injection the gastric contents were again aspirated and titrated for free acid. The stated times for aspiration were selected because experience showed that they would bracket the peak secretion in practically all cases.

Examination of Stools—Three consecutive examinations of the stools for occult blood after a three day period during which the patient was fed a meat free diet represented a routine practice. Every patient

whose stools gave a positive benzidine reaction was given a proctoscopic examination to rule out a lesion of the lower sigmoid colon, rectum or anus as a source of blood. This procedure was especially indicated since a low grade chronic proctitis or cryptitis was an occasional sequel to the dysentery that affected many of the troops. A positive benzidine reaction for occult blood in the stools was of value in the diagnosis of peptic ulcer only when interpreted in the light of other findings and only when sources of blood other than peptic ulcer had been eliminated.

Acid Test—The patient strongly suspected on clinical grounds of having a peptic ulcer but with no lesion of the upper gastrointestinal tract demonstrable by x-ray examination presented a challenging problem. Fractional gastric analysis and examination of the stools for occult blood were usually of extremely doubtful value as aids to diagnosis in such cases. In our search for additional diagnostic procedure we turned to the acid test described by Palmer of Chicago.⁵ The results of this test in our hands gradually assumed increasing importance in differentiating between a functional gastrointestinal disturbance and true peptic ulceration. This test is based on observation that the instillation of 200 cc of hydrochloric acid in physiologic concentration induces in a patient with a fresh, sensitive peptic ulcer the typical epigastric distress that is so characteristic of an active lesion and that this distress is promptly relieved by aspiration of the acid solution followed by instillation of a solution of sodium bicarbonate. Perhaps the greatest advantage of this procedure in our experience was that while the patients might have learned from others the usual pain-food-ease symptom complex they had little opportunity to know just what liquids were being instilled or just what the characteristic response should be in the event that an ulcer was present. This test we performed by completely emptying the stomach with a Levine tube and then instilling 200 cc of 0.3 per cent hydrochloric acid. At the end of a fifteen minute period the stomach was again emptied and left in this state for fifteen minutes. At the end of the second fifteen minute interval 200 cc of 2 per cent solution of sodium bicarbonate was introduced and the patient was observed closely during a final fifteen minute period. The character, the locality and the severity of distress noted during each fifteen minute period were recorded. In the presence of a sensitive ulcer the response was usually striking and unmistakable. For one third of the patients in whom typical distress was induced there was positive x-ray evidence of ulcer. In a control series composed largely of patients suffering from symptoms attributable to functional gastrointestinal disturbances no such clearcut responses were encountered. Distress was sometimes observed in this control group but it was invariably vague and ill defined.

There is another possibility that should be mentioned. It is conceivable that in severe ulcerative gastritis typical epigastric pain might be elicited by the instillation of acid. The need for gastroscopic studies to determine this point is evident.

RESPONSE TO THERAPY

As an additional aid in the differentiation between pain due to an active ulcer and pain due to a functional disturbance, response to therapy was given considerable weight in totaling the balance of evidence for a

⁴ Palmer, W. L. Peptic Ulcer, in Cecil, Russell L. A Textbook of Medicine, ed 5, Philadelphia, W. B. Saunders Company, 1940.

⁵ Palmer, W. L. The "Acid Test" in Gastric and Duodenal Ulcer. J. A. M. A. 88: 1778-1780 (June 4) 1927.

against an organic lesion. The patient suspected of having a peptic ulcer was given hourly feedings of 120 cc of equal parts of evaporated milk and water with gradual addition over the course of the ensuing two weeks of soft bland foods. If this dietary management failed to control symptoms, resort was had to a continuous alkaline milk drip as recommended by Winkelstein for a period of not less than forty-eight hours. One liter of equal parts of evaporated milk and water to which had been added 50 Gm of sodium bicarbonate was given over a period of eight hours. This was given at the rate of about 30 drops per minute. The response to this therapy in all the patients with ulcer was both prompt and gratifying. At the end of forty-eight hours it was usually possible to substitute hourly milk feedings for the continuous drip and to keep the patients comfortable and free of symptoms except for a few with severe pain at night. In striking contrast, those patients with a functional gastrointestinal disturbance, and there were many, almost uniformly failed to express any clearcut or more than transient relief of their symptoms. Perhaps the explanation of this significant difference in response to therapy lies in the fact that the majority of patients with functional gastrointestinal distress gave other evidence of an underlying severe emotional disorder. Their symptoms may well have represented an unconscious neurotic reaction which served to prolong hospitalization and provide an escape from an unpleasant situation.

ARMY GENERAL CLASSIFICATION TEST

The relationship between the results of the army general classification tests and diseases of the digestive tract are discussed in greater detail elsewhere. In brief, these tests are designed to determine a man's ability to learn the duties of a soldier. On the basis of his score a soldier is placed in one of five broad classes called army grades. These grades give an indication as to his relative ability to learn as compared with the average soldier. When the percentage of patients with ulcer in each grade was compared with the theoretical standard, it was found that there was no significant deviation. This contrasts sharply with our findings in patients suffering from functional disturbances of the digestive tract.

DISPOSITION

The question of disposition of the patient who develops a peptic ulcer in the field soon became an important one. At first there was an inclination to give the patient a thorough course of dietary treatment and rest and then return him to duty. Experience proved the inadvisability of this practice. In one instance a soldier with a clearcut clinical picture but only minimal deformity of the duodenum on x-ray examination was returned to duty symptom free after a course of what would generally be considered adequate medical care. His duties were ordinarily light, he had access to abundant food and fresh milk and was living under garrison conditions. This man remained well and symptom free for nearly two months. At the end of this time there was a sudden increase in responsibility, long hours, irregular meals and heavy physical labor. He endured these changed conditions for about ten days, at the end of which time he was brought into the hospital with an acute perforation of an ulcer in the duodenum. He was operated on successfully and recovered. This is but one case. However, this experience emphasizes the importance of removing the patient having peptic ulcer from the field and returning him to the zone of the

interior where facilities are adequate for their care and rehabilitation. Therefore it has become the policy of the disposition board of this hospital to recommend the transfer to a general hospital in the zone of the interior every patient known to have or strongly suspected of having a peptic ulcer.

CONCLUSIONS

- 1 The ulcer problem in the combat area presents new difficulties peculiar to military personnel.
- 2 The clinical history while of definite value cannot be relied on solely in the diagnosis of peptic ulcer.
- 3 Positive x-ray diagnoses in the field are limited by (a) technical difficulties and (b) the examination of patients before the pathologic process has become extensive.
- 4 Analysis of gastric contents and examination of stools for occult blood are of but limited value in the diagnosis of peptic ulcer.
- 5 A study of the results of the army general classification tests of patients with peptic ulcer indicates that there is no significant deviation from the normal.
- 6 The acid test described by Palmer and the relief following continuous alkaline milk drip therapy have proved to be two useful adjuncts in making the diagnosis of peptic ulcer.
- 7 The soldier with a peptic ulcer should be removed from the combat area as soon as is practicable after the diagnosis is made.

CALCIUM PANTOTHENATE FOR HUMAN ACHROMOTRICHIA

LACK OF VALUE ON PROLONGED ADMINISTRATION

IRVIN KERLAN, MD

AND

ROBERT P. HERWICK, MD, PhD

WASHINGTON, D C

A recent editorial¹ in *THE JOURNAL* entitled "Vitamins for Gray Hair" reviewed the experimental evidence relating to the use of pantothenic acid and para-aminobenzoic acid to prevent and correct nutritional achromotrichia.

Controlled clinical evidence to substantiate the view that pantothenic acid will restore color to hair in human beings is not available in the scientific literature. Two articles appearing in a monthly magazine directed to the interests of women in running a household refer to the value of pantothenic acid in this respect. Irrespective of the lack of controlled clinical evidence, calcium pantothenate has been offered to the public as an effective agent for restoring color to gray hair. It is interesting to note that in the labelings of products containing calcium pantothenate the representations for the substance are directed to all persons who desire to restore "the original color to the hair." Dissemination of information concerning this alleged virtue of calcium pantothenate has been rapid and widespread.

In view of the absence of corroborative clinical data which would serve to establish that calcium pantothenate can restore color to human gray hair it was decided to conduct a long-term study using calcium pantothenate

From the Federal Security Agency Food and Drug Administration.
1. Vitamin for Gray Hair, editorial, *J A M A* 125:102 (1942).

to observe its effect on graying hair. It was recognized at the outset that the isolation of calcium pantothenate and its introduction for general use had been within the past few years. Consequently there had been only a relatively short period of time in which reliable observations could have been made of the change, which is reported to require from one to six generally three months to manifest its effect in human beings.

Studies on black haired experimental animals indicated that deprivation of pantothenic acid in diets may produce among other changes, a patterned graying of young animals. This observation could not, however, be considered applicable to man since it has not been demonstrated as pointed out by Gordon,³ that the human diet is deficient in pantothenic acid as a single factor. Furthermore, the production of graying had been accomplished only in young animals, yet the use of this article for human beings is designed for adults who have gray hair.

Recently Brandaleone, Mann and Steele⁴ reported a study on the effect of calcium pantothenate on the gray hair of human beings. Their findings indicate that calcium pantothenate did not effect a change in hair color. Vorhaus, Gompertz and Feder⁵ using calcium pantothenate in large doses by intramuscular injection, concluded that calcium pantothenate had "no effect upon gray hair present."

CLINICAL STUDY

Twenty-one white women and 6 white men ranging in age from 34 to 62 years volunteered to take calcium pantothenate for a six months period. Two white women and 4 white men in the age group 29 to 62 years offered to serve as controls by providing hair samples during the same period but they did not take calcium pantothenate. These persons represented degrees of decrease of hair pigment varying from beginning graying to 'all white'. Loss of hair color had been present for varying periods (none less than ten years except 1 person who had noted rapid graying in the past three years). Several persons indicated that premature graying was a family trait. The subjects were government employees who were in the salary group who could afford and did have adequately varied diets. Discussion of recognized sources of pantothenic acid in foods provided an opportunity to suggest to the subjects the advisability of using these foods in increased amounts in planning menus. No records of daily food intake were kept, since there is no evidence in the literature that human beings are spontaneously deficient in pantothenic acid. Furthermore the need for pantothenic acid in human nutrition has not been established. No studies of pantothenic acid levels in the blood, its absorption or excretion were undertaken.

In order to use an objective approach to evaluate the color change in the hair and thereby keep to a minimum the subjective element, it was decided to have color analyses made of the samples of hair collected before, during and at the close of the period of observation. Such color comparisons were to be made by an expert in the field of color analysis. In this manner it would be possible to obtain the unbiased opinion of one trained in color analysis who could employ without prejudice such color tests as were required and accepted, since this observer would be unfamiliar with the volunteers.

Representative samples could readily be obtained on men by collecting their hair cuttings. In the case of women, however, it was realized that during the six months period of observation no samples might be obtained. Thus it was found necessary to cut a sample of hair from a representative area of the scalp, and as the hair regrew the area was recut to furnish samples for comparison with the original sample cut shortly before the person began taking calcium pantothenate. The most significant samples were the original and the one obtained after completion of taking calcium pantothenate for six months.

For ease of administration, each user was provided daily with 2 tablets of calcium pantothenate (micro biologic analysis of the product revealed an average composition of 102 mg of d-calcium pantothenate per tablet). The generally recommended dose in the labeling of preparations of calcium pantothenate is 1 tablet (10 mg) per day. In order to provide an adequate amount of the substance, the suggested daily intake was doubled. Tablets were taken under personal supervision so that a daily opportunity to observe the persons was provided.

Observation of the volunteers throughout the period of the study revealed no change in hair color. None of the individuals reported a significant hair color change; however, several persons, particularly in the age group 34 to 40 years, felt that there was an increase in hair grayness. All the persons were satisfied that calcium pantothenate did not restore hair color. Several persons remarked that friends and acquaintances occasionally did state that they could see a "darkening" in the color of the hair, but the users themselves were unable to detect any change. It was generally acknowledged that this spurious change in hair color was occasioned by a variation in hair styling. It is obvious that frequent observation of the subjects is required in order to reach reliable conclusions. In one woman a "yellowing" effect was noted near the free ends of an isolated white band of her hair. This effect was observed after using calcium pantothenate several months. Follow-up two months after the termination of the study revealed that this yellow cast was appearing over the ends of other gray hair areas. The nature of this change is unknown, but apparently it is not significant since not infrequently such a yellow cast is noted in white and gray hair. Furthermore the color change does not represent the original color of this woman's hair. It should be pointed out that one of the volunteers in this study had had a yellow cast in her hair for several years and was interested in observing if any change could be effected by using calcium pantothenate. No change was brought about. No significant changes were observed in the control group.

4 Brandaleone, Harold, Mann, Elizabeth, and Steele, J. M. Effect of Calcium Pantothenate and Para Amino Benzoic Acid on the Gray Hair of Humans, *Proc. Soc. Exper. Biol. & Med.* 53: 47-49 (May) 1943.

5 Vorhaus, M. G., Gompertz, Michael L., and Feder, Aaron. Chemical Experiments with Riboflavin, Inositol and Calcium Pantothenate, *Am. J. Digest. Dis.* 10: 45-48 (Feb.) 1943.

It is of interest to note that 2 women complained that their fingernails were breaking and chipping more easily than usual. They questioned whether use of calcium pantothenate was a causative factor. In view of these complaints it is doubtful whether pantothenic acid can be ascribed as having a beneficial effect on the fingernails.

Color determinations of the respective samples for each of the 33 subjects, made by Dorothy Nickelson, color technologist, Research and Testing Division, Cotton and Fiber Branch, Food Distribution Administration, United States Department of Agriculture, employing visual comparisons to Munsell color standards by a method essentially the same as that described by Judd and Kelly,⁶ "revealed no significant trend of color change for any individual whether under treatment or control." These color measurements corroborated the clinical impression gained by frequent observation of the hair of the volunteers.

SUMMARY AND CONCLUSIONS

1 Twenty mg of calcium pantothenate was administered daily for six months to 27 white men and women with graying hair. Close observation of the hair of these individuals revealed no significant change.

2 Color measurements of representative samples of hair obtained from each of the subjects at the outset during and at the conclusion of the study revealed no significant color change.

3 From these findings, from the clinical evidence available in the literature and from personal communications, it is concluded that calcium pantothenate is of no value in the restoration of color to gray hair.

Beginning of Orthopedics as a Specialty—The beginning of orthopedics as a specialty, and the establishment of the first orthopedic hospitals can be traced back to the interest of the eighteenth century French humanitarians in crippled and deformed children. Jacques Mathieu Delpuch, professor of surgery at Montpellier was the real founder of the specialty. In 1828 Delpuch published a treatise entitled *Orthomorphy*, which is the earliest comprehensive discussion of bone and joint deformities. He also planned and built a charming orthopedic hospital in the country between Montpellier and Toulouse. A contemporary of his, Johann Georg von Heine, an instrument and brace maker to the faculty of the University of Wurzburg, founded an orthopedic institute in that city in 1816 which had a leading role in the development of the specialty in Germany. Heine's nephew, Bernard Heine, graduated in medicine from Wurzburg and became its first professor of orthopedics in 1838. In England the first orthopedic hospital was founded at Birmingham in 1817. William John Little, an eminent orthopedic surgeon who himself had a clubfoot, founded the Orthopedic Institute of London in 1837. Subsequently called the Royal Orthopedic Hospital, it became the leading British institution for the care of the crippled poor. In America two pioneer orthopedic surgeons both established special orthopedic clinics in the same year, 1861. Lewis A. Sayre of New York organized a clinic at Bellevue Hospital, and Buckminster Brown of Boston opened a small private hospital, the Samaritan Hospital. Two special orthopedic hospitals were shortly founded in New York: the Hospital for the Ruptured and Crippled in 1863 and the New York Orthopedic Dispensary and Hospital in 1866—Hargensen, C. D. and Floyd Windham, F. B. A Hundred Years of Medicine, New York, Sheridan House, Inc. 1943.

AUTOPSY NERVE GRAFTS IN PERIPHERAL NERVE SURGERY

CLINICAL APPLICATION, "GLUE" SUTURE TECHNIC

ROLAND M. KLEMMER, M.D.

ST. LOUIS

CAPTAIN R. DEAN WOOLSEY

MEDICAL CORPS, ARMY OF THE UNITED STATES

AND

NILSON T. DE REZENDE, M.D.

Instructor in Surgery, St. Louis University School of Medicine

ST. LOUIS

Repair of peripheral nerves with preserved cadaver grafts has become one of the most promising fields of modern surgery. The results of animal experimentation and clinical application appear to justify this claim. This communication is a preliminary report dealing with the clinical application of experimental work of one of us¹ to 3 cases in which preserved cadaver grafts have been used to repair large defects in human peripheral nerves.

To appreciate the failures of peripheral nerve surgery in the past, the pathologic anatomy of the traumatized nerve must be considered. When a nerve is severed there is considerable hemorrhage into the injured area. In the process of repair this hemorrhage is replaced by scar tissue and neuroma formation even when directly sutured. The consensus is that neuromas are largely due to the outgrowth of the proximal end of the neurons trying to find their way down the distal portion of the nerve. That this is not the entire picture is suggested by the fact that when a peripheral nerve is not immediately sutured a neuroma will usually form at both the cut ends of the nerve. The proximal neuroma is usually larger than the one on the distal portion of the nerve, which suggests that neuroma formation is largely due to hemorrhage with scar formation and that growth of axons seeking their normal pathways increases the size of the neuroma on the proximal side.

The phenomenon of scar formation is largely responsible for failure to achieve a functionally perfect result in many cases in which primary suture of the nerve is possible. Even when the finest needles and suture material are used and when the sutures are placed very carefully, they will traverse the substance of the nerve causing microscopically enormous injuries to nerve bundles about the periphery of the nerves. This increases the element of hemorrhage and scar tissue formation. The problem is more difficult when a functionally important peripheral nerve is grossly damaged or destroyed so that a considerable gap exists between the severed nerve ends.

During the twentieth century several attacks have been made on the problem of peripheral nerve surgery. Fresh homografts from other small nonessential nerves have been utilized. Grafts of fat fascial flaps and nerve flaps all have been tried with equally discouraging results. The first forward step was contributed by Brillance and Ducloux in 1932. These men were able to show excellent results in bridging a gap in the facial

from the Neurological Service of Roland M. Klemmer, M.D., Professor of Surgery, Chairman of the Division of Neurosurgery, University School of Medicine.

2. Brillance, C. A. and Ducloux, J. B. *Arch. Otolaryngol.* 75: 1 (1932).
19. *Tr. Am. Otol. Soc.* 1931: 1 (1931).

nerve in the fallopian canal of baboons. They have also been able to bridge a similar gap in man by use of a graft taken from the external cutaneous nerve of the thigh of the same patient. No sutures were used, the graft being kept in place by careful dressing and by the bony configuration of the canal.

Bentley and Hill³ in 1940 reported their experiences using sutures in their cases of experimental grafts from other animals of the same species, in the monkey. This was the first step in the solution of the technical problem of bridging gaps in peripheral nerves without the use of heroic measures such as nerve transplantation and plaster casts to hold extremities in positions favorable to nerve union.

Young and Medawar⁴ of Oxford in the same year suggested the use of coagulable plasma with the consistency of "glue" to replace the sutures of severed nerves. They advocated the use of a fortified cockerel plasma with chick embryo extract as the clotting agent. This plasma "glue," rich in fibrinogen, was placed in the gap forming a bridge between the severed ends

nerve injuries. On May 29, 1941 at the Harvey Cushing Society, Rochester, N. Y., and in 1942 at the annual meeting of the New York State Medical Society one of us¹ reported the results of the use of sections of "cadaver grafts" (sections of peripheral nerves of cadavers) in bridging gaps of various lengths in sciatic nerves of monkeys, dogs, cats and rabbits. This work was carried out at the Yale University School of Medicine Laboratory of Physiology and extended over a period of two years' time, thus allowing a rather extensive study of the problem.

A search was made for a better and more accessible "glue" than any before suggested. The results indicated that 50 per cent pure acacia or acacia fortified with vitamin B and B complex caused the least tissue reaction and gave the best result. The free nerve ends and graft were first anchored lightly in place by "bridges of silk," silk sutures placed over the free nerve ends and the graft into surrounding tissue but not entering any of these structures.

In further prosecution of this work at the Mayo Clinic in the Experimental Institute in conjunction with Dr. H. E. Essex, Rezende⁶ utilized the modified "ear window" of Clark to study this problem further. It was found that in rabbits the first observable phenomenon at the site of a "glued cadaver graft" of the posterior auricular nerve of a rabbit was an outgrowth of capillaries from the proximal side across the gap into the graft. This capillary framework was followed by the outgrowth of the severed axons. This study suggests that the role played by the acacia glue is merely that of a cement holding the graft in place. The cadaver graft merely acts as a framework of tubes for ingrowth of the severed axons.

CLINICAL APPLICATION

Three clinical applications of these experiments have been completed at the present time. In others the elapsed time is not great enough to include in this report. The grafts and glue have been prepared as suggested by Rezende¹. The glue used was 50 per cent acacia prepared by slowly dissolving the acacia in boiling distilled water. This percentage gives a thick glue when cooled to room temperature. The glue may be autoclaved without deleterious effect.

The cadaver grafts were obtained under practically sterile conditions in the autopsy room. The sections of nerves were handled very gently and all connective tissue was removed as completely as possible. The grafts were placed on cardboard by means of thumb tacks and then suspended in solution of formaldehyde U. S. P. diluted 1:10. They were left in this solution for from ten to thirty days, after which time they were washed in distilled water for forty-eight hours. They were transferred to 75 per cent alcohol two or three days before the proposed operation. One half hour before the operation they were transferred from the alcohol to saline solution.

The injured nerves were carefully exposed and the damage to the nerves was assayed. Flaps of the nerve sheaths were then carefully dissected from both sides of the neuroma proximally and distally (fig. 1B). These flaps were then sutured to the surrounding connective tissue before the removal of the neuroma. This keeps the proximal and distal nerve sections anchored and allows a stable position for location of the graft. The neuroma is next resected distally and

Fig. 1—A, neuroma, and the allantoic membrane as future bed. B, flaps of the nerve sheath dissected from both sides of nerve, proximally and distally. C, prepared graft cut to size. D, prepared graft in place—glued. E, allantoic membrane placed around nerve ends and graft.

and forming a trestle for the growth of the proximal axons into the sheaths of the distal fragments of the severed nerves.

Tarlov and Benjamin⁵ of New York found considerable fibrosis at the site with the use of this material when they repeated these experiments. They in turn evolved the method of using autologous plasma fortified with autologous muscle extract. They state that this is easy to prepare and that this material causes less inflammatory reaction and subsequent scar formation at the site. They concluded, however, that this material was not practicable when there was any tension on the severed nerve ends and that silk sutures were probably better in these cases.

The subject of peripheral nerve surgery was made most important in this country on Dec. 7, 1941. Statistics from various and sundry wars have shown that from 1 to 3 per cent of war casualties have peripheral

⁶ de Rezende, N. T. Work to be published.

proximally. Light pressure is exerted on the severed nerve ends to stop hemorrhage. When this has been done the graft is carefully cut to fit, a new safety razor blade being used for this purpose. A bed of allantoid membrane (insultoric) is next placed around the nerve ends, and the graft is placed on this bed between the severed ends (figs 1A and C). Two or three drops of 50 per cent acacia prepared as described are then placed on each junction. A second layer of allantoid membrane is then placed over the graft and the proximal and distal ends of the peripheral nerve, which at this stage must be in good alignment (fig 1D). This is allowed to stand for a few minutes. The wound is closed carefully in layers with interrupted silk sutures. An ordinary snug fitting bandage is used and no further immobilization is necessary.

The first patient was operated on on Aug 27, 1942

CASE 1—V S, a white girl aged 8 years, admitted to St Louis City Hospital on March 4, 1942 because of a rather large laceration of the right popliteal space, had fallen from a swing at 5:45 p.m. on the date of admission and had cut the right popliteal area on a sharp piece of tin. A tourniquet had been applied to stop the bleeding, and the child was brought to the hospital. Tetanus antitoxin and perfringens antitoxin were administered in the accident room.

The patient complained bitterly of pain behind the right knee. The temperature was 99 F, pulse rate 124 and respiratory rate 26. Blood pressure was 120 systolic, 80 diastolic. Examination of the extremities showed a 4 inch laceration extending horizontally across the right popliteal space. This extended through the skin and subcutaneous tissues, exposing the deep structures. The skin margins were

Fig 2—Sensory loss before operation

widely separated. The patient was taken to the operating room and the laceration was sutured in the usual fashion after lebridement. The tendons of the semitendinosus and the gastrocnemius muscles were found to be severed. The common peroneal and the sural nerves had also been cut. The cut ends of the tendons and of the common peroneal nerve were approximated and sutured with fine silk. The leg was placed in an anterior plaster splint with 120 degrees flexion. The wound healed nicely and the sutures were removed on March 20. The patient was discharged on April 17, 1942 with a walking right ankle stop brace. She continued to have a foot drop and sensory defect (fig 2).

She was readmitted on Aug 3, 1942 complaining of continued foot drop and sensory defect. On August 26 a nerve graft operation was done.

Under drop ether anesthesia, iodine and alcohol preparation an incision was made over the popliteal fossa on the right to expose the common peroneal nerve. The deep fascia was incised and retracted laterally. The neuromas were then encountered at the separated ends of the common peroneal nerve. These were freed. All bleeding was controlled. A bed of amniotic membrane (insultoric) was prepared beneath the nerve ends and clipped in place with Klemme clips. The neuromas were then excised and a prepared graft was adjusted between the cut ends of the nerve. These were held in place with bridges of silk as described which did not penetrate the nerve sheath. The wound was then closed loosely with interrupted silk sutures. A dry gauze dressing was applied.

The patient's postoperative course was uneventful and she was discharged from the hospital on Sept 11, 1942. At the present time she is walking with a slight limp but without a brace. She can skip, dance and runs easily on both feet. The

sensory defect is clearing rapidly and the size of the calf of the leg is almost equal to that of the left leg. She is now receiving hot-wet applications to the limb twice daily.

CASE 2—C S, a white man aged 35, was first admitted to St Louis City Hospital on July 28, 1942 complaining of pain and loss of sensation in the fourth and fifth fingers of the left hand. Ten months before admission he had suffered a bullet wound in the left chest while cleaning a rifle. From that time on there had been sensory and motor changes in the left hand including paralysis of the fingers, some difficulty in movement of the arm and anesthesia of the little and ring fingers. Three days before admission his left little finger began to swell at the tip. This swelling gradually extended proximally. Along with this swelling he experienced considerable pain. The patient was chronically addicted to alcohol, drinking about a pint of whisky a day. Examination showed an area of anesthesia involving the lateral half of the lower arm extending over the lateral half of operation.

Fig 3—Sensory loss before operation

the ring finger and the little finger. There was a scar over the knuckle of the little finger, and the phalanx distal to this was swollen and red. There was no pain on pressure over this finger. The temperature on admission was 100.6 F and was normal thereafter. The swelling of the finger rapidly subsided. The laboratory work was entirely normal. The patient was discharged on Aug 1, 1942.

He was readmitted on Oct 26, 1942 for a nerve graft operation. The operation was done on November 16.

With the patient under ether anesthesia an incision was made along the lateral border of the left pectoralis major muscle. The brachial plexus, axillary artery and vein were exposed. A neuroma of the ulnar nerve was isolated and separated from the axillary vein. Nerve sheath flaps were dissected free from proximal and distal ends of the neuroma and sutured in place. The neuroma was then excised, leaving a gap in the nerve about 2 cm long. This was replaced by a cadaver nerve graft. Fifty per cent acacia was then used to cement the nerves together. A piece of allantoid membrane (insultoric) was then placed over the graft and the severed nerve ends. The wound was closed carefully in layers with interrupted silk sutures. No drain was used.

The postoperative course was completely uneventful. The section of neuroma removed consisted of fibrous tissue con-

Fig 4—Sensory loss before operation.

taining bundles of medullated nerve fibers. The fibers stained poorly and contained many vacuolated areas.

The patient was discharged on Nov 23, 1942. When last seen he was beginning to have return of function in his finger.

CASE 3—N T, a white youth aged 18 referred by Dr D J Zerbolio of Benld Ill, admitted to St. Mary's Hospital on Jan 15, 1943 complained chiefly of paralysis of the fingers of his left hand for six and one half months. He had fallen and cut his left wrist on a plate glass window. The wound was immediately sutured a day or two later. He had lost

sensation in his little and ring fingers and weakness of those fingers. Physical examination was negative except for the left hand. There was a sensory loss over the lateral half of the ring finger and over the entire little finger and the hypothenar eminence. There was a loss of abduction and adduction of the fingers. A 2½ inch scar showed on the volar aspect and the ulnar side of the forearm. The laboratory work was negative. An operation was done on Jan. 18, 1943.

With the patient under avertin with amylene hydrate and ether anesthesia an incision was made through the old scar. The ulnar nerve was isolated and a rather large neuroma was found in the nerve. Four small strips of nerve sheath were sutured to the surrounding tissue and the neuroma was excised. The prepared nerve graft was then placed between the cut ends on a bed of allantoic membrane (insultoric). Fifty per cent acacia was placed over the nerve junctions and the wound was closed in layers with interrupted black silk sutures. A dry gauze dressing was applied.

The patient was discharged on Jan. 22, 1943. At the present time he is doing well. Complete function has not returned to the fingers but it is still too early to judge the result.

COMMENT

Time of Operation—The majority of surgeons have emphasized that there are two optional times for operation: one as soon as possible after the injury has occurred, the other, after wound healing is complete. In the first three hours following an injury it is possible in the majority of cases to change contaminated wounds into clean wounds and to carry out repair. Healing is thus effected by primary union. If an open wound heals without infection a secondary operation can be performed three or four weeks later. If the original injury is complicated by infection, a secondary operation must be postponed until the wound is clean and all inflammatory reaction has disappeared completely. We believe that the advent of the sulfonamides and streptomycin will mean a great advancement in this kind of surgery, sterilizing the infected wounds and permitting an early operation.

The question of how to treat a freshly severed nerve is a difficult one. If there is any tension on the nerve we believe that a graft, if available, should be used to bridge the gap. However, a graft can always be applied later if immediate suture is unsuccessful.

Graft—Professor Lavrentjev of Russia has studied many aspects of the regeneration of peripheral nerves and claims to have found evidence of a "chemicomotor role" of the distal (peripheral) segment in attracting nerve fibers to itself. Using pieces of spinal cord as transplants for bridging gaps after nerve lesions he found that the best results were obtained by using nerve treated with formaldehyde, since this was quickly vascularized and delayed the proliferation of the connective tissue elements of the scar.

Sutures—We do not believe that it is possible to suture the epineurium of nerves without laceration of a great number of the axis bundles, even with the finest needles and finest silk. Of course, in small nerves it is impossible to suture without laceration of the majority of nerve fibers. For these reasons we think that the acacia "glue" reinforced with "flaps of the neuroma" and if necessary also with the "bridge of silk" is the ideal way to keep the graft and nerve ends in good alignment.

Control of Hemorrhage—In surgery of peripheral nerves the control of hemorrhage is of paramount importance if scar tissue formation is to be prevented. Some surgeons use an inflated blood pressure cuff on the extremity located proximal to the wound during the

operation. We have not used this procedure but prefer to control the hemorrhage of each vessel that bleeds. Before excising the neuroma the assistant should apply light pressure with a small piece of cotton soaked in saline solution to the proximal and distal portion of the nerve after the neuroma has been excised. This pressure should be sufficient just to stop any bleeding from the severed nerve. The graft is then placed in the gap between the two ends of the nerve and at the same time two or three drops of acacia "glue" are applied to the junction of the graft and severed nerve to act as a cementing agent. If the intraneural hemorrhage is prevented, the tendency toward neuroma formation is obviated and an ideal situation is created for the neurotization of the graft. These findings will be reported in greater detail in a later communication.

Physical Therapy—From observations made with the ear window of Clark, it seems that measures directed toward the promotion of vascularization of the graft give the most aid in obtaining a successful clinical result. Accordingly, two weeks after operation we advise application of moist heat to the grafted area. Lavientjev⁷ has also emphasized that "the only means found for accelerating nervous regeneration is heat."

Immobilization—A simple snug fitting bandage was used for immobilization in each of these 3 cases. We believe that elaborate systems of splints are unnecessary and harmful. In the first place they are likely to produce trophic ulcers unless very carefully applied. In the second place moderate activity of the extremity promotes vascularization of the nerve graft and more rapid growth of nerve fibers.

Massage and Motion—Gentle massage and motion are begun not earlier than two weeks postoperatively.

Electrotherapy—The results of investigations are not in agreement about the effects of electrical stimulation in retarding the rate of atrophy following denervation of muscles. Fischer⁸ and the Guttmanns⁹ reported favorably, but Choi and his co-workers¹⁰ obtained discouraging results. Hines, Thomson and Lazere¹¹ at the University of Iowa concluded that "artificial stimulation retarded the rate of atrophy and enhanced the regeneration of denervated muscle." We have used gentle stimulation in some instances and we are of the opinion that it is of value in bringing about more rapid return of function after nerve grafting has been done.

CONCLUSIONS

The first clinical application of cadaver graft, using 50 per cent acacia to glue the severed ends together has been made. The first patient already has a good clinical result with return of motor and sensory function. The second patient is already beginning to get return of function. The third case is too recent to make it possible to judge.

The postoperative care of a patient operated on with a peripheral nerve injury is a very important factor for recovery. Any method that can increase the local circulation will be of primary importance in the process of physiologic recovery.

PERITHYROIDITIS

A DISTINCT ENTITY

JOSEPH L. DECOURCY, M.D.
CINCINNATI

As I¹ pointed out in a recent article on the subject, I feel that Riedel's struma is the result of a previous perithyroiditis which causes a partial constriction of the vessels entering the thyroid gland. Another case of Riedel's struma, in which I lately operated, has served to strengthen my belief that such is the etiology of this condition and has in addition, focused my attention on perithyroiditis as a distinct entity.

My own observations on a series of cases, including the one here reported in detail, have convinced me of the etiologic relationship between perithyroiditis and woody thyroiditis. I believe that as a result of the perithyroiditis the fibrous growth characteristic of the disease begins outside rather than within the thyroid gland. Histologic evidence indicates that, as a sequel to perithyroiditis and its complications, there results partial occlusion of the blood vessels entering the gland with subsequent formation of the fibrous tissue characteristic of Riedel's struma. In other words, because of the perithyroiditis it appears to me that Riedel's struma is a vascular rather than a glandular disease.

From all of this evidence I believe that perithyroiditis warrants more consideration than seems to have been given to it in the past. Indeed, little if anything has been written about perithyroiditis. A search of the available medical literature has failed to reveal any reference to such a condition. A similar search of the current textbooks on medicine, surgery and pathology was also in vain. This paucity of information is rather surprising in view of the fact that for some time surgeons have recognized evidence of perithyroiditis in the form of adherent muscles and perilymphangitis.

It is quite possible that the clinician has been diagnosing cases of this type as acute nonsuppurating thyroiditis when in reality they were cases of perithyroiditis. If perithyroiditis really occurs as a clinical entity—and the evidence which I have accumulated indicates that it does—what are the acute symptoms and what are the pathologic changes?

The thyroid gland as observers know is covered by a network of lymphatic vessels and lymphatic glands. Although this concept was never established by proof it was thought at one time that the thyroid secretions left the thyroid gland by way of these channels. However, evidence has been found that lymphangitis is present in many cases of goiter even those of a chronic nature. In perithyroiditis lymphangitis is often a concomitant part of the elements contributory to Riedel's struma.

Since becoming interested in the subject of perithyroiditis I have encountered a number of patients with diffuse enlargement of the thyroid gland (from two to three times normal size) who gave a history of an acute onset with varying degrees of fever and occasionally chilliness. These patients complained of pain in the thyroid region and the thyroid gland was tender on palpation. However there was no visible evidence of inflammation. Moreover when these patients were seen as late as eight weeks after onset of their illness

the lobes were still tender although the temperature and the blood count had returned to normal. These symptoms are typical and in my opinion characterize the entity perithyroiditis.

Because of the continued tightness of the throat, the persistent enlargement of the thyroid and the nervousness of these patients I have operated on a number of them shortly after subsidence of the acute symptoms, that is after periods ranging from two to twelve weeks. In all instances the basal metabolic rates were normal or only slightly elevated. Thus, in 2 cases previously reported¹ the average basal metabolic rates were plus 16 and plus 20 respectively.

One recent case is rather interesting and indicative of the course of events during and following perithy-

Fig 1—Section of a small artery showing hypertrophy of the media with reduction of the lumen and a surrounding collar of dense hyalinized connective tissue. Hortege silver impregnation stain.

roiditis. The temperature ranged from 99 to 101.6 F for a period of eight weeks without any evidence of suppuration. Chemotherapy was instituted but did not influence the course of the disease. After eight weeks of hospitalization during which the patient was kept in bed high voltage roentgen therapy was applied. Following a few treatments the temperature returned to normal and the tenderness disappeared. Nonetheless the hard swollen condition of the gland persisted with the consistency of woody thyroiditis. Six months have now elapsed but the patient refuses operation and complains only of some tightness around the throat and slight nervousness.

The other cases in which surgical intervention has been undertaken including those already reported and the one to be herein discussed presented the typical

picture of Riedel's struma with adherent muscles surrounding the gland. The evidences of perithyroiditis included pseudo giant cells, arteriolar sclerosis and other distinctive characteristics of the disease. These are

quite apparent in the photomicrographs of histologic sections previously and herewith presented.

The following report of a case which I was able to follow through to a satisfactory conclusion serves to substantiate my views not only with regard to perithyroiditis as an entity but also with respect to its relationship in the etiology of Riedel's struma.

REPORT OF CASE

C. N., a married woman aged 33, who entered the Good Samaritan Hospital on Feb. 13, 1943, developed what seemed to be a mild sore throat three weeks prior to admission while in Detroit. She had daily chills after which her temperature went to 103 F. A physician treated her for three weeks, during which time the chills and fever continued. Before leaving for Detroit, and one month prior to the onset of the present illness, she had a complete physical examination at the clinic. The patient reported that she had no enlargement of the thyroid gland and no symptoms pertaining to the gland prior to her present illness.

When examined at the Good Samaritan Hospital in Cincinnati, where she reported as a result of an exacerbation of her condition, her temperature was found to be 101.4 F., the pulse rate 120 and the respiratory rate 20. Blood examination revealed hemoglobin 85 per cent, red blood cells 4,500,000, white blood cells 14,500, polymorphonuclears 82 per cent, lymphocytes 16 per cent, monocytes 1 per cent and eosinophils 1 per cent. The urine had a specific gravity of 1.017, was negative for albumin, sugar and acetone, and showed 4 white blood cells per high power microscopic field and no red blood cells.

The patient had three chills followed by fever on three successive days after admission to the hospital. After this her temperature returned to normal without treatment.

An electrocardiogram taken on February 14, the day after admission, showed definite sinus tachycardia with one premature ventricular systole. X-ray examination of the chest on the same day gave negative results.

Blood examination on February 15 revealed hemoglobin 87 per cent, red blood cells 4,500,000, white blood cells 8,200, polymorphonuclears 77 per cent, lymphocytes 19 per cent, eosinophils 1 per cent, monocytes 3 per cent and stab cells 8 per cent.

Blood cultures made on February 15, 16 and 17 were negative after eighteen hours, forty-two hours and three days. A blood culture made on February 18 was negative after forty-two hours. The blood was negative for malarial parasites, typhoid bacilli, *Brucella melitensis* and *Brucella abortus* of bovine origin.

A tentative diagnosis made by the house physician was "possible subacute bacterial endocarditis."

On February 17, four days after her admission, I examined the patient in consultation. She was a rather small woman who did not look particularly sick. Her temperature was 99.2 F., the pulse rate 110, the respiratory rate 18. There was a slight tremor to the outstretched fingers. A mild systolic murmur was heard at the apex of the heart. Ocular signs were absent. Two basal metabolic tests gave rates of plus 16 and plus 14.

The thyroid gland was about two to three times the normal size and of hard consistency. The lobes were tender to the

Fig 3.—Section of precapillary arteriole showing it surrounded by dense hyalinized connective tissue. Hortege silver impregnation stain.

touch. The tenderness extended laterally and upward beyond the lobes. The patient stated that she had noticed the tenderness over her neck when, one week after the onset of her illness, her nephew, aged 5, had thrown his arm at her neck. There was no external evidence of inflammation.

A diagnosis of Riedel's struma was made. Strong solution of iodine was given in the dosage of 10 drops three times a day for one week.

Operation performed on February 24 confirmed the diagnosis both grossly and microscopically. The muscles were found to be adherent over both lobes of the gland, the process extending well up the sides. The microscopic diagnosis was made by Dr. William German, pathologist to the Good Samaritan Hospital, who reported that section showed extensive diffuse fibrosis replacing gland bearing tissue. There were progressive strangulation of lobules, abundant new formation of connective tissue and numerous pseudo giant cells. The small arterioles showed extensive sclerosis with perivascular sclerosis. Some of this had been of rapid and recent origin and had resulted in small focal areas of necrosis, similar to those found in necrotizing arteriolonephrosclerosis. The amount of actual lymphoid tissue was scanty. There was pronounced sclerosis of the gland capsule. No cancer was present. The diagnosis was Riedel's struma (struma fibrosa of the thyroid gland).

The patient made an uninterrupted convalescence. By March 3 the heart murmur had disappeared.

COMMENT

This is the fifth case of Riedel's struma with an acute onset seen by me during the past eighteen months. Three of these cases have been verified by operation. Two were reported previously. Two of the patients refused operation.

In addition to the acute onset, all of these cases presented certain common characteristics which I consider to be a part of the perithyroiditis entity. Among these may be included such symptoms as fever of varying degrees (often with chilliness), pain or other discomfort in the thyroid region, absence of visible inflammation and persistence of tenderness in the lobes after other symptoms, more especially the fluctuations of temperature, have subsided. In general, the history is negative as to previous involvement or dysfunction of the thyroid gland.

The basal metabolic rate appears to be unaffected or at most only slightly elevated. Subsidence of acute symptoms has generally been followed by nervousness, fine tremors, continued tightness of the throat and persistent enlargement of hardened consistency. Riedel's struma has been the end result as verified post-operatively in 3 of 5 cases displaying this train of symptoms.

The surgeon seldom sees Riedel's struma until the acute phase has subsided. I have been fortunate enough to secure good case histories which enabled me to obtain a clearer picture of the complete syndrome. On the basis of my observations it seems likely that in diagnosing acute nonsuppurating thyroiditis observers have been witnessing the onset of Riedel's struma. None of the glands affected with this disease suppurate. It has been my experience that suppurative thyroiditis develops within a comparatively short time and that it is usually accompanied by cellulitis of the neck. In contrast early fibrosis was the rule in the cases under discussion.

One must not overlook the fact that during the acute phase of perithyroiditis the febrile symptoms are so mild as to cause many of the patients to go untreated. Not infrequently the condition is diagnosed as grip or cervical adenitis. The soreness disappears and the patient leaves the physician's care only to seek a surgeon later.

In view of these findings the explanation which I offer is that primary perithyroiditis with the adherent edematous muscles and lymphangitis partially occludes the blood vessels entering the thyroid gland and causes

the entity known as Riedel's struma. In brief, Riedel's struma is a vascular rather than a glandular disease.

This contention is borne out by both the gross and the microscopic appearance of the excised glands, but more especially by the histologic sections. In the photomicrographs presented it may be seen that the picture strikingly resembles that of the kidneys described by Goldblatt and his associates² in which the renal arteries were partially constricted.

While on the subject I should like to revert briefly to the role of iodine in the etiology of Riedel's struma. In the previous discussion¹ I expressed doubt that iodine entered the picture. These doubts have been strengthened as a result of further observations. Iodine does not seem to be a causative factor, because in a recent case of eight weeks' standing the patient had been given no iodine before the onset of the disease.

SUMMARY AND CONCLUSIONS

Perithyroiditis is a distinct entity with a definite train of symptoms and sequelae. Perithyroiditis is the etiologic factor in the formation of Riedel's struma. Additional evidence submitted tends to confirm the view that Riedel's struma is a vascular rather than a glandular condition.

ELECTRONMICROGRAPHY OF MURINE POLIOMYELITIS VIRUS PREPARATIONS

CLAUS W. JUNGEBLUT, M.D.

AND

JAQUES BOURDILLON, M.D.

NEW YORK

Following isolation and identification of the murine strain of SK poliomyelitis virus¹ in this laboratory, subsequent work has been concerned with purification of the infectious agent. By using physical and chemical methods of extraction and concentration, highly potent virus preparations were obtained from infected mouse brains. These preparations possessed an appreciable degree of physical homogeneity, as determined by ultracentrifugation, and reacted in precipitin tests with specific antiviral sera.² The purified material seemed to offer a good opportunity to gather additional information on the morphologic characteristics of the infectious agent by means of further study with the electron microscope. For the same purpose there were also available tissue culture preparations of SK murine virus. The latter were examined in the unpurified state.

The work to be described in this paper was carried out in collaboration with the staff of the Physics Divi-

sion of the Research Laboratories of the American Cyanamid Company at Stamford, Conn. The instrument employed was the commercial RCA model which permitted primary magnifications between 1:5,000 and 1:8,000. The original negatives were further enlarged to final scales of from 1:14,500 to 1:20,000.

Fig. 1—Sample of purified SK murine virus prepared by extraction from infected mouse brains and suspended in a 0.01 per cent solution of sodium phosphate, $\times 14,500$.

EXPERIMENTAL WORK

Materials—Purified SK murine virus obtained from infected mouse brains (270th-320th passage) by chemical extraction and sedimentation in the ultracentrifuge, as described in detail elsewhere,² was dialyzed in a cellophane bag against distilled water or dilute buffer for twenty-four hours at icebox temperature. The sample, when tested for potency in mice, had an intracerebral titer of between 10^9 and 10^{10} minimum lethal doses. A control preparation, made from normal mouse brain by using the same methods of purification, was similarly dialyzed. It was noninfectious for mice. SK murine tissue culture virus was obtained by growing the strain for three days at 37°C in a medium consisting of minced embryonic mouse brain in ox serum ultrafiltrate. The composition of this medium and the properties of SK tissue culture virus have been fully described before.³ The supernatant fluid of SK murine virus tissue cultures (200th and subsequent passages), when tested for potency in mice gave an intracerebral titer of 10^6 minimum lethal doses. These virus preparations, without preliminary purification of any kind, were dialyzed against distilled water for twenty-four hours in the icebox. A control preparation made from noninoculated, but incubated, tissue culture medium was similarly dialyzed.

Electron microscope preparations were made from the various virus and control materials described by

applying a drop of fluid to a collodion film which, after thorough drying, was exposed to the electronic beam. In the case of each preparation, at least four different fields were selected and photographed. Focusing was greatly handicapped by the fact that most preparations contained little or no material that could be seen directly on the fluorescent screen.

Results—A considerable number of pictures were thus obtained. Most of these showed a confusing multitude of bodies of varying size and shape or amorphous aggregates. Because of their haphazard occurrence in both viral and control material, it was obvious that none of these forms bore any manifest relationship to the infectious agent. In certain photographs of virus preparations, however, structures were observed which could not be found in any of the several control preparations examined. The electronmicrograms of these particular virus preparations together with photographs of corresponding control preparations are reproduced in the accompanying illustrations.

Figure 1 shows an electronmicrogram ($1 \times 14,500$) of a sample of purified SK murine virus prepared by extraction from infected mouse brains and suspended in a 0.01 per cent solution of sodium phosphate. It reveals the presence of a large number of small, round or elliptic, fairly well defined bodies, some of which occur without distinct grouping whereas others seem to be aligned in pairs or short chain formation. These

Fig. 2—Another sample of the preparation shown in figure 1 previously treated with 0.25 per cent calcium chloride solution. $\times 14,500$.

bodies appear to be all of more or less uniform size measuring slightly less than 0.5 μ in diameter on the picture, which would correspond to an actual size of 25 to 30 millimicrons. In figure 2 is shown an electronmicrogram ($1 \times 14,500$) of another sample of the same preparation, but previously treated with 0.25

³ Sanders, Murray, and Jungeblut, C. W. Cultivation of the Murine Strain of SK Poliomyelitis Virus, J. Exper. Med. 75: 631 (June) 1942.

per cent calcium chloride solution. This picture presents, among much aggregated material, bodies of essentially similar morphology except that they possess a slightly sharper contour. Figure 3 is an electronmicrogram ($1 \times 14,500$) of a control sample of material obtained by extracting and concentrating normal

Fig. 3—Control sample of material obtained by extracting and concentrating normal mouse brain $\times 14,500$

mouse brain by chemical and physical procedures analogous to the procedure employed for the purification of infected mouse brain. This picture shows the presence of a large number of ill defined, heterogeneous structures mostly of dissimilar size, none of which bear any morphologic resemblance to the bodies observed with the two virus preparations mentioned before.

The next three illustrations deal with electronmicrograms obtained from unpurified tissue cultures of SK murine virus and un inoculated tissue culture preparations. Figure 4 is an electronmicrogram of SK murine tissue culture virus ($1 \times 20,000$). It shows among much heterogeneous material the presence of numerous thin but rather long filamentous threads which sometimes lie so close together that they appear to form a network. Occasional threads seem to contain, at certain points along their axis or at the end, small spherical or elliptic bodies which give to the entire structure the appearance of beads or buds. The individual threads seem to be all of the same width, i.e., approximately 20 millimicrons, but of different length, varying from about 75 to 5,000 millimicrons or perhaps even more. Another electronmicrogram ($1 \times 20,000$) of the same virus preparation is presented in figure 5. It shows essentially the same forms though less numer-

ous and seemingly of two different densities. The same characteristic beaded or budded appearance is well recognizable in this picture. Figure 6 is an electronmicrogram ($1 \times 14,000$) of the supernatant fluid of un inoculated tissue culture medium which had been incubated for five days at 37 C. The picture shows the presence of numerous bodies of variable size and shape but none which resemble the threadlike structures observed with the two virus preparations mentioned before. Another control preparation was made by growing a strain of western equine encephalomyelitis virus in the same type of tissue culture medium as was used for the propagation of the two strains of murine poliomyelitis virus. An electronmicrogram was obtained from this preparation (titer 10^4 minimum lethal doses intracerebrally). It showed a large number of very poorly defined small spherical bodies but failed to reveal the presence of any threadlike structures.

COMMENT

The observations made in this work are presented merely to preserve an experimental record. In view of the present difficulties in properly interpreting electronmicrograms of viruses it would be premature to make any attempt to evaluate this information. In certain experiments, however, the biologic activity of murine poliomyelitis virus (SK strain) was evidently associated with the presence in the infective material of certain fairly well defined structures as determined by photography with the electron microscope. Since these structures occurred only in virus preparations and not in corresponding virus free control material, it

Fig. 4—SK murine tissue culture virus, reduced from a photograph with a magnification of 20,000 diameter

is conceivable that we were dealing with the infectious unit itself. On the other hand it must be pointed out that such structures could be found only in very few virus preparations out of a great many examined and that the ordinary means of identification by serologic methods were missing.

Two different types of structures were observed, first, elliptic bodies, occurring singly or in short chains, and, second, filamentous threads, which, in some instances at least, seemed to be made up of a series of such bodies held together by some cohesive material in linear association. The bodies had a diameter of

Fig 5 Virus preparation shown in figure 4, reduced from a photograph with a magnification of 20,000 diameters

between 25 and 30 millimicrons. The diameter of the threads measured about 20 millimicrons while their length appeared to vary considerably from about 75 to as much as 5,000 millimicrons. The first form was observed with purified virus preparations extracted from infected mouse brains, the other with unpurified tissue culture virus preparations. It is impossible to say at present whether the two forms are in some way connected with different biologic stages of the virus or whether the difference is an artificial one, peculiar to the methods of handling the respective virus preparations. The dimensions of these structures—in one diameter at least—are appreciably larger than has previously been computed for the virus on the basis of ultrafiltrations.⁴ They correspond closely, however, with calculations derived from the sedimentation rate in the ultracentrifuge.²

After this paper had been submitted for publication there became available the report of a similar investigation carried on by a group of Swedish workers (Gard, Petersen, Svedberg and Tiselius) in Uppsala.⁵ A verbal quotation (page 143, lines 4-16) from Dr Gard's monograph of the pertinent data concerning

Theiler's virus of mouse encephalomyelitis (obtained from infected mouse brains) or of human poliomyelitis virus (obtained from spinal cords) follows

The micrographs of murine neurovirus showed mainly long filaments, almost exclusively single fibers in a loose network with wide meshes. Now and again impurities appeared to be adsorbed to the fibers, forming bead-string-like structures. The tendency to bundle formation seemed to be less pronounced. In the human neurovirus preparations a finely dispersed substance predominated. It seemed to be rather uniform with regard to particle size and shape, forming rounded elements of about 10 millimicrons in diameter. In the bulk of this substance single fibers were embedded, sometimes branched but seldom in netlike arrangement. Bundles were never observed. A third component in the shape of rounded particles might have been present, very difficult to distinguish from aggregates of the main component.

The apparently close agreement between the two sets of observations—one dealing with natural murine and human strains, the other with a mouse adapted strain of human poliomyelitis virus—seems noteworthy.

SUMMARY AND CONCLUSIONS

1 Electronmicrograms of SK murine poliomyelitis virus, obtained either from infected mouse brains or from tissue culture preparations, were made.

2 Purified virus preparations from mouse brain showed fairly clear and uniform particles 25 to 30 millimicrons in diameter, while noninfectious control material contained only structures of ill defined morphology.

Fig 6—Supernatant fluid of uninoculated tissue culture medium which had been incubated for five days at 37° C. slightly reduced from a photograph with a magnification of 14,000 diameters

3 Unpurified virus tissue culture fluid showed long threadlike structures measuring 20 by 75 to 5,000 millimicrons, which were not found in noninfectious control material.

4 The nature of the described structures at present must remain undetermined.

MEASURING EYE FLASH FROM
ARC WELDING

V EVERETT KINSEY, PH D

DAVID G COGAN, M D

AND

PHILIP DRINKER, Sc D

BOSTON

In our shipyards today we are employing over 100,000 welders. These workers and their neighbors have a certain amount of exposure to ultraviolet radiation, although every effort is made to supply and use suitable eye shields, goggles and screens. About 40 per cent of the calls at our shipyard dispensaries are because the patient has received what he thinks may be an "eye flash".¹

Our purpose in the present study was to derive a practical rule whereby one can estimate in terms of time, intensity of radiation and distance the safeness of any exposure to a welding arc.

Verhoeff and Bell² showed that the ultraviolet radiations responsible for ocular lesions in rabbits were shorter than 305 millimicrons and that about 2×10^6 erg seconds per square centimeter were required for a minimal effect. They also showed that the biologic response varied with the duration of the exposure and inversely with the square root of the distance. That is, a four second exposure was twice as severe as one of two seconds, but an exposure at 4 feet was only one fourth as serious as one at 2 feet. Moreover, they found that within a twenty-four hour period the effects of repeated dosages were additive. The sources of radiation in their experiments were a mercury vapor lamp and a magnetite arc. No one, to our knowledge, has determined the exposure from a welding arc necessary to produce minimal ocular symptoms in human beings.

For our exposure studies we employed a welding machine set to operate on straight polarity at 300 amperes and 35 volts. Five-sixteenths inch Hubbard covered electrodes were used and welding was performed on a half inch thick block of iron.

In order to make our data readily applicable to operating conditions an ordinary Weston photographic light meter was calibrated in foot candles and used as a measure of dosage. The intensity of the radiations varied three or four fold from moment to moment, so that it was necessary to estimate the average intensity throughout the exposure period. The average meter reading in foot candles multiplied by the duration of exposure in minutes is used as an "exposure" coefficient or time-intensity factor. The units thus become foot candle-minutes.³

The dosage measured by the light meter is due almost entirely to the visible portion of the spectrum rather than to radiations in the ultraviolet shorter than 305 millimicrons, which are the ones known to be responsible for the deleterious ocular effects. Thus for light meter readings to be a valid index of the ocular hazard it is necessary to know whether the quantity of ultraviolet radiations bears an essentially constant ratio to

the quantity of visible radiations under various conditions encountered in welding. Through the courtesy of Drs H C Rentschler and Arthur W Ewell of the Westinghouse Lamp Company, who provided us with a tantalum photoelectric cell⁴ and click meter, we were able to measure the amount of ultraviolet radiation from arcs produced at several different amperages and by electrodes from six different manufacturers. The results of all these experiments are summarized in table 1. It will be observed from the table that there is considerable variation in output between electrodes but that the average readings of the light meter did parallel the amount of ultraviolet radiation as indicated by the number of clicks on the click meter. Moreover, the ratio of the amount of ultraviolet to visible radiation from the electrodes of various manufacturers appeared to be approximately the same. It will be noted that several of the types of electrodes tested produced somewhat greater amounts of radiant energy. Considering the variability

* Each click of the meter represents 220 micro watt seconds per square centimeter of equivalent 2.537 angstrom radiation.

of the readings for any given make of electrode and the few tests made we doubt whether this has any significance.

All the eyes were checked before exposure to make sure they were normal and again approximately eighteen hours after irradiation. The eyes were examined with the biomicroscope with and without fluorescein staining. Mottling of the cornea as revealed by the use of a Placido disk was found to be the most sensitive index of injury. Signs of exposures just in excess of those required to produce minimal injury were keratitis epithelialis, conjunctival and ciliary injection and, in human beings, epiphora. In none of our experiments was the dosage used sufficient to produce visible infiltration of the cornea. The chief symptoms noted by the men exposed were foreign body sensation and photophobia. To show roughly the severity of the injury a grading system of — through +++ is used in the tables which summarize the results. A ± indicates mild mottling with minimal diffuse staining. A +++ indicates a fairly definite keratitis epithelialis with conjunctival and ciliary injection and in human beings sensation of a foreign body.

The first experiments were performed on animals the eyes being held open manually for the exposure.

⁴ The upper wavelength limit of the tantalum cell is about 1.000 angstrom, the lower limit is about 2.600 angstrom and its sensitivity is about 2.600 angstrom.

⁴ The distance at which measurements were made makes no difference since the unit incorporates foot candles.

Ten rabbit eyes were irradiated with doses having exposure coefficients below 100 foot candle-minutes. No appreciable injurious results followed. A second group of rabbits and three dogs were then exposed. Table 2 summarizes these results. It will be seen that an exposure coefficient of 333 foot candle-minutes is required

All exposures were at 7 feet

to produce observable signs in rabbits and that considerably larger doses, namely an exposure coefficient of 600 foot candle-minutes was required to produce the only injury observed in dogs.

Table 3 illustrates the results on human volunteers. The subjects (young men) held the exposed eye open throughout the period of irradiation and were asked to fix on an object about 15 degrees to the side of the arc in order to avoid production of bothersome scotomas. It will be observed that an exposure coefficient of 200 foot candle-minutes is required to produce minimal ocular damage consistently in men. In actual practice this required, with one exception, a thirty second exposure at a distance of 7 feet. From the fact that a twenty second exposure (exposure coefficient 133) sometimes produced damage, we believe that approximately 150 foot candle-minutes would represent the average exposure coefficient necessary to produce minimal ocular injury in 50 per cent of the subjects. With these minimal exposures the average time at which initial symptoms were noted was eight to ten hours after the exposure.

Provided it was possible to determine total exposure time accumulated by an individual throughout a working day, repeated exposures being approximately additive during a twenty-four hour period,² it should be possible from the foregoing data to estimate the probable ocular hazard in any given welding situation by simply measuring at night the intensity with a light meter calibrated in foot candles. For example, if it is assumed that a person working near where welding is being performed might accumulate a fifteen minute exposure in the course of a day, one would predict a definite danger of ocular symptoms if the intensity at this distance from the arc was equal to 10 foot candles or more.

(i.e. $\frac{150 \text{ foot candle minutes}}{15 \text{ minutes}} = 10 \text{ foot candles}$)

Since daylight intensities vary from about 100 foot candles to several thousand, it would be impracticable to measure changes of 10 foot candles. That is sunlight would offer too much interference. However, if the

arc intensities are measured at night or in a dark room interference can be avoided.

Chiefly because of the uncertainty in estimating the probable time a person might be exposed, it would appear safer in practice to provide protection in the form of shields or goggles unless a safety factor of about tenfold can be allowed. Thus, after estimating the maximum time which an individual might be exposed in the course of a day, preferably by direct inspection under working conditions, an exposure coefficient of the order of 15 foot candle-minutes would seem to afford a sufficient margin of safety that the danger of ocular symptoms would be nil.

It is evident that time of exposure required to produce symptoms is not consistent with the general idea of "flash" exposures, and therefore the term appears as a misnomer. Thus there appears to be little need to provide protection for persons who will be exposed but momentarily. Moreover, since ordinary crown and flint glass are essentially impermeable to radiations shorter than 305 millimicrons, it follows that any spectacle or goggle having a thickness of 2 millimeters or more, whether colored or not, will afford practically complete protection from electric arc welding provided some shield is available to prevent lateral exposure.

Theoretically it would be possible to give these rules for safe welding in terms of distance from the arc. To do so one must assume that arcs are constant as to intensity. If the intensity varies, as it will in changing from an arc drawing 100 amperes to one drawing 300, the distance factor would have to be altered. It is better, we believe, to measure the effect of the arc by means of the light meter, which combines the effects of distance and intensity into a single figure.

Shipyards using a single type of welding machine and a constant intensity presumably can estimate the distances which apply to their particular conditions.

All exposures were at 7 feet excepting the last one, which was at 3 1/2 feet

SUMMARY

A light meter calibrated in foot candles was found to give an adequate, although arbitrary, measure of the dosage of radiation from electric welding arcs which produce ocular injury. The exposure to such arcs necessary to produce minimal ocular signs and symptoms in rabbits, dogs and human beings has been measured. As to time and intensity of radiation, a minimum standard of safety for men in the neighborhood of electric welding arcs has been recommended as one that required to produce minimal ocular effects.

ACUTE VIRUS INFECTION WITH
NERVE ROOT INVOLVEMENT
SIMULATING APPENDICITIS

CAPTAIN WINFIELD L. BUTSCH

MEDICAL CORPS ARMY OF THE UNITED STATES

AND

LIEUTENANT COLONEL JAMES C. HARBERSON

MEDICAL CORPS ARMY OF THE UNITED STATES

This report is concerned with acute pain and tenderness occurring in the right lower abdominal quadrant in 50 patients who did not have appendicitis. The admission diagnosis in all patients except 2 was acute appendicitis. This series of 50 patients were young men observed during a six month period at a station hospital. Among the early patients in the group 13 were operated on and in each instance a normal appendix was removed. As more patients were seen and the findings pieced together the syndrome became more apparent and fewer patients were treated surgically. None of the latter patients exhibited any signs or sequelae of appendicitis in their subsequent course.

ONSET

The abrupt onset was one of the salient features of this infection. Young men who had felt perfectly well at work, playing football sitting in a classroom or taking a walk while off duty were suddenly seized with a knifelike abdominal pain which caused many of them to double up. This pain awakened them out of a deep sleep and on one occasion struck a medical officer just as he was reaching for his alarm clock. This medical officer had undergone appendectomy some years before. His observations on himself were helpful in providing orientation.

Nausea and vomiting practically always occurred in the first few hours, which added to the suspicion of appendicitis. There was no prodromal period of malaise or lack of appetite. Often a full meal had been eaten just before the pain began. The patients did not complain of a cold preceding the onset with any more frequency than one would expect colds during the fall season of the year.

This pain struck in the right middle or lower part of the abdomen as a rule. It might also be felt in the right loin. It was localized at the onset. There was no shifting or localization of initial generalized pain as in appendicitis. In the latter type of pain occurs our treatment is immediate operation for appendicitis. Coughing or deep respiration reproduced the pain. Frequently the patient stated that the whole right side of the abdomen was sore and tender. The pain did not radiate.

A striking feature of this pain was the fact that it was always worse at night. This was true for every patient. A number of the patients were able to remain on duty for several days because the pain was lessened when they were up and about. They stated that as soon as they lay down after duty the pain became severe and grew worse through the night. It was after an uncomfortable night of pain that they sought admission to the hospital. At times the pain was extremely severe and persisted for hours, requiring morphine for relief.

Nausea and vomiting were confined to the first few hours. Only in 2 instances were these symptoms present later. The patients did not experience malaise

or a febrile sensation. Their appetite was only fair but they did eat. Urinary symptoms and diarrhea were not present.

PHYSICAL FINDINGS

The flushed face presenting a brick red appearance formed a strong impression and immediately aroused suspicion of the nature of the complaint. The brick red appearance was not limited to the malar eminences but involved the entire face. A faint generalized flush of the skin might be present. The conjunctivas were likewise heavily injected supporting the impression that this was a systemic infection. The patient had a drowsy appearance and turned on his side to sleep when not questioned by the examiner.

The appearance of the soft palate was characteristic. It was entirely covered with a raised plaque or edematous mucous membrane of a salmon pink. On closer inspection small papular elevations with yellow centers could be seen interspersed over this area. The pharynx was not involved. The patient had no sensation of sore throat. This finding was noted in the soft palate of 48 of the 50 patients. It was less prominent when the complaint was of more than a week's duration.

The patient could always point to a definite area on the abdomen where the pain had its onset and was maximal. In 30 of the cases this was to the right of the umbilicus (area I of fig. 1). The pain was felt to a lesser extent throughout the right side and in the right flank. This was also true of the tenderness. The tenderness could often be traced along the course of the tenth intercostal nerve. In eliciting the tenderness one noted that there was definite soreness in the skin. The patient flinched and voluntarily tightened the abdominal muscles the moment the skin was touched. When the patient's confidence was gained one could often palpate deeper and deeper without causing more pain. Hyperesthesia was commonly found throughout the right side of the abdomen. In 3 cases hypesthesia was noted on the right side. True muscle spasm was not found. The abdomen was noteworthy for its scaphoid appearance and laxity to gentle palpation after the first flinching of the patient was overcome.

Certain characteristics designated this pain as that of nerve root. It was reproduced in the area to the right of the umbilicus by coughing or deep breathing. Careful flexing of the neck without causing the abdominal muscles to tighten reproduced the pain in the same area in about half of the cases. Asking the patient to sit up with knees extended reproduced pain in the abdomen and in the flank simultaneously. In addition the previously mentioned nocturnal exacerbations fitted in well with this conception.

The next most common abdominal area where the pain was felt was the right lower quadrant (area II of fig. 2). The maximum of pain and tenderness was found in this area in 17 patients. This area lay slightly below and nearer to the inguinal ligament than McBurney's point, though this was not striking enough to constitute a significant differential observation. Here again the fact that deeper palpation did not increase pain is of interest. The right upper quadrant as shown in area III of figure 2 was the site of maximal pain and tenderness in 3 patients.

Two of the patients were admitted with the diagnosis of acute cholecystitis. The illness of one later followed the course of a virus pneumonia and the x-ray appearance was consistent with that diagnosis. In every

patient pain and tenderness were elicited all over the right side of the abdomen but were maximal in the areas just discussed. Many of the patients referred pain to the right side of the abdomen when the left side was palpated. This finding is of interest because of the absence of acute appendicitis.

Eight patients with similar histories and physical findings were seen and not included in this group. The reason is that the pain was maximal either in the epigastrium, the left upper quadrant of the abdomen or to the left of the umbilicus and would not be confused with the pain of appendicitis. These patients showed the same clinical findings aside from the site of the pain as did the reported group. The areas in which the pain and tenderness were found are illustrated in figure 3. Undoubtedly, localization of pain in these sites was just as common as localization in the right side of the abdomen. However, circumstances prevented their coming to our attention. Patients with pain in these areas were less likely to consult their infirmary phy-

16 patients with a leukocyte count of over 10,000 and but 4 with a polymorphonuclear percentage over 75.

Lumbar punctures were done on 5 patients. No increase in spinal fluid pressure or cell count was found.

Two patients had x-ray findings consistent with a diagnosis of virus pneumonia, which rapidly cleared. In other instances in which roentgenograms of the chest were taken they showed no pulmonary involvement.

The urine was always normal.

COURSE

When these patients were first seen in the late summer and early autumn the pain was neither as severe nor as prolonged as it was later in the autumn when all respiratory diseases were more frequent and severe. At first the pain rarely lasted longer than twelve or twenty-four hours. In the late autumn and winter the average duration was from a week to ten days. One patient continued to have severe pain every night for

Fig. 1—Areas where pain and tenderness were most commonly found

Fig. 2—Areas where pain and tenderness were next most commonly found

Fig. 3—Areas on left side of abdomen where pain and tenderness were found

sician. If they consulted him he was less likely to send them to the surgical ward with a diagnosis of possible appendicitis. The group we are reporting were seen for the most part in one surgical ward.

During August, September and early October these patients uniformly showed no elevation of temperature or of pulse rate. This was of value in arriving at an opinion. But as the common infections of the respiratory tract became more prominent in the late autumn they were at times combined with this syndrome. Thus a temperature as high as 102 F and a pulse rate of 100 were found because of associated rhinitis, sinusitis or tonsillitis.

LABORATORY FINDINGS

As has been stated, the temperature was usually normal or elevated only when there was associated infection of the respiratory tract. In the series there were only 12 patients with a temperature above 98.6 F and only 3 with a temperature above 100 F.

The tendency of the white blood cell count was to be normal with a normal or less than normal percentage of polymorphonuclear leukocytes. Here again mixed infection somewhat confused the picture. There were

eighteen days without relief. At this time the abdomen was explored with no abnormal findings. A normal appendix was removed.

Without exception the patients stated that they felt fairly well during the day but that they had severe pain at night while they remained in the hospital. They did not have nausea and vomiting after the onset. They were able to eat fairly well, and some were able to be up and about. They did not have elevated temperature in the hospital unless there was associated rhinitis or tonsillitis.

The nocturnal pain was sometimes severe enough to require morphine. Costovertebral nerve block was induced with procaine hydrochloride in 5 patients. Relief lasting only six to eight hours was gained from this procedure. Herpetic or other lesions of the skin were not seen.

COMMENT

We wish to emphasize that no syndrome, however well defined, which includes pain and tenderness in the right lower quadrant of the abdomen can ever be easily assumed not to be appendicitis without the most careful and repeated observations. At four and eight hours

intervals the history, physical findings and white blood cell count were rechecked until appendicitis no longer seemed to be a possibility.

Early in the series many of the patients were operated on as we were becoming familiar with the syndrome and were not certain of our differential diagnosis. The abdomen was carefully explored. The appendix, the cecum and the terminal part of the ileum were found to be normal in each instance. Particular attention was given to the appearance of the glands in the mesentery of the terminal part of the ileum. They were not enlarged or inflamed in any instance. Thirteen of the 50 patients were operated on. Observation of the progress of the remaining 37 patients did not suggest appendicitis.

Four patients who previously had undergone appendectomy were admitted with this syndrome. Their pain was equally severe, and in one it lasted as long as thirteen days.

We were particularly cautious when confronted with patients who gave a history of epigastric or generalized abdominal distress which localized later in the right lower quadrant. We were also suspicious of patients with a leukocyte count over 12,000 and a polymorphonuclear percentage over 75. Despite the presence of the other features of this syndrome an acutely diseased, suppurative appendix was removed from each of 2 patients who presented the stated findings indicative of appendicitis.

Two patients had two admissions to the hospital with this syndrome. One of these showed a definite change in symptoms twenty-four hours after the second admission. He developed nausea and vomiting during the night and in the morning and a sharply localized deep tenderness over McBurney's point. A tightly distended appendix that was beginning to show signs of redness was removed.

We realize that definite evidence that the infection was due to a virus is almost entirely lacking. The fact that we had not seen this syndrome before entering a station hospital where virus infections have been common, plus the characteristically low white blood cell count, plus the singling out of the nerve roots for involvement, plus the appearance of the soft palate have influenced us tentatively to call this a virus infection for purposes of cataloguing it.

SUMMARY

The following features of an acute infection with pain and tenderness in the right lower quadrant of the abdomen aid in distinguishing it from acute appendicitis:

1. Sudden, sharp onset of localized knifelike pain maximal immediately.
2. A flushed face and a punctate erythematous edema of the soft palate suggesting a systemic infection.
3. Pain that is worse on lying down and at night like pain of nerve root irritation.
4. Pain intensified by coughing, flexing the neck and flexing the trunk like pain of nerve root irritation.
5. Tenderness over the course of intercostal nerves.
6. Absence of elevation of either the total or the polymorphonuclear leukocyte count.

Two case reports are presented.

REPORT OF CASES

CASE 1—A man aged 26 entered the hospital with the history that two days previously while sitting in a classroom he suddenly suffered a severe knifelike pain in the right mid-abdomen. He had eaten a good lunch before the onset of the pain. That night he vomited once. There had been no diarrhea or urinary complaints. The pain had continued in the same area since onset. It was much worse at night. In addition the entire right side of the abdomen was sore.

The patient appeared to be in good general condition. His entire face was flushed presenting a brick red color. The conjunctivas were injected. The mucous membrane of the soft palate was edematous and of salmon pink. There were numerous papular elevations with yellow centers throughout the palate. The pharynx was not inflamed. The abdomen had a scaphoid appearance and was soft. To the right of the umbilicus was a tender area the size of the palm of the hand. The tenderness was superficial and caused the patient to flinch and tense his abdominal muscles as soon as the skin was touched. The entire right side of the abdomen from the costal margin to the inguinal ligament was sore to the touch. The tenderness could be traced around the flank to the costovertebral angle. Palpation of the left side of the abdomen caused the pain to be referred to the right side of the abdomen. Flexing the neck caused the pain to be accentuated in the right side of the abdomen.

His temperature on admission was 99 F. The red blood cell count was 5,530,000 per cubic millimeter and the hemoglobin content 90 per cent. The white blood cell count was 8,700 per cubic millimeter with 64 per cent polymorphonuclears, 33 per cent lymphocytes, 1 per cent basophils and 2 per cent monocytes. The urine was normal.

The patient continued to have pain in the right side of the abdomen for the next seventeen days. Repeated examinations and blood counts were made. None of them were suggestive of acute appendicitis. This pain was always worse at night. X-ray examination of the kidneys, ureter and bladder showed no abnormality. The abdomen was explored. The appendix, the cecum and the terminal part of the ileum were normal. There were no enlarged lymph glands in the mesentery of the terminal part of the ileum. The appendix was removed.

The postoperative course was uneventful. The patient did not complain following the operation. He was up and about on the first postoperative day and left the hospital on the twentieth postoperative day.

CASE 2—A man aged 20 entered the hospital because of a sudden sharp pain which developed in the right lower quadrant of the abdomen twenty-four hours previously while he was on a march. During the first day of the pain it was continuous. That evening there were nausea and vomiting, and the pain became worse. The pain was still present the following morning when the patient entered the hospital.

The patient was healthy appearing. His face was a brick red and the conjunctivas were injected. The soft palate was edematous and of a salmon pink. Small papules with yellow centers were seen scattered throughout the soft palate. The pharynx was normal. The abdomen was soft and scaphoid. The maximum pain and tenderness were in an area somewhat below and nearer to the inguinal ligament than McBurney's point. The tenderness could be traced about into the loin. Flexing the neck reproduced the pain in this area. Flexing the trunk reproduced the pain both in the right loin and below McBurney's point.

The temperature on admission was 98 F. The white blood cell count was 9,100 per cubic millimeter with 65 per cent polymorphonuclears, 32 per cent lymphocytes and 2 per cent mononuclears. The results of a urinalysis were within normal limits.

After forty-eight hours stay in the hospital the pain had entirely disappeared, the flush left the face and the patient was discharged.

Station Hospital Camp Carson, Colorado

Clinical Notes, Suggestions and New Instruments

CONTACT DERMATITIS FROM HAIR LACQUER

J. B. HOWELL, M.D., DALLAS, TEXAS

The success and beauty of the "up sweep" hair style is made possible by a quickly drying lacquer. Although this form of hair dress has been popular in the South for about five years, a sudden outbreak of dermatitis from this cause appeared only during the last month. Whether or not this is due to a change in the constituents of lacquer has not been determined. Downing¹ recorded an incidence of eczema of the ramus of the left jaw and eyelids due to nail polish. Prior to the onset of the dermatitis this patient recalled spilling a bottle of ink eradicator. After mopping up the fluid with a cloth she noted

Contact dermatitis of the ears, sides and back of the neck from hair lacquer pads

itching of the face. Two months later her hair was set and sprayed with lacquer. "That night she suffered from severe itching and redness of the sides of the face." Patch tests with the hair lacquer and ink remover elicited positive reactions. Downing concluded that the substances contacted in nail polish, ink eradicator and hair lacquer were allergenically alike. No other case of sensitivity to hair lacquer or to both nail polish and hair lacquer in the same person could be found in reports published during the past seven years.

In the private practice of Dr. Bedford Shelmire and myself, a young housewife was observed with a dermatitis of the eyelids. This eruption was a classic example of an eczematous contact dermatitis due to nail polish. The diagnosis was con-

firmed in forty-eight hours by the appearance of an erythematous plaque at the patch site where nail enamel was applied to the neck. The dermatitis cleared promptly following removal of the nail lacquer.

One month ago this patient was again seen with an acute contact dermatitis of three weeks' duration. The ears and back of the neck were pruritic, swollen and covered with fine erythematous papules. The dermatitis was said to have appeared one week after she started using hair lacquer for the first time. Contact tests were made with all of the materials used on her scalp. A negative test reaction followed the application of a soap used for shampoo, a hair rinse and hair tonic. A positive reaction was noted in twenty-four hours at the site of the contact test with Renee hair lacquer. The dermatitis cleared promptly after discontinuing its use.

This presented an interesting problem of whether the patient had developed a totally new and added sensitivity or was merely sensitive to some ingredient common to nail polish and hair lacquer, as recorded by Downing. She was rather definite about an interval of seven days between the initial spraying of lacquer on her hair and the appearance of the dermatitis. This suggested an incubation period of sensitivity to hair lacquer. Had she already been sensitive to this liquid the latent period would have been only twenty-four to forty-eight hours and certainly less than five days.

Ten women who had previously been treated for the usual eczematous contact dermatitis from nail polish and who gave positive patch reactions to nail lacquer tests were tested with hair lacquer. Five stated that they used their lacquer occasionally without resulting dermatitis. Patch tests with Renee, Admiracion and Henri Maison hair lacquer were uniformly negative. A dermatitis could not be produced in these nail polish sensitive women by applying hair lacquer directly to a recently healed site of previous nail lacquer dermatitis, as the eyelids.

A few days after observing the aforementioned patient we saw a second housewife with a healing eczematous dermatitis involving both ears, the eyelids and the back of the neck. This had appeared twenty-four hours after having sprayed lacquer on her hair. Three similar incidents had been experienced. A positive reaction followed a patch test with the Henri Maison brand of hair lacquer which she had employed. The reaction to contact tests with Renee hair lacquer and Revlon nail polish were negative. The eruption healed promptly and she remained well after avoiding hair lacquer. Nail enamel was worn continuously by this woman during attacks of dermatitis.

Hair lacquer is applied as the last step in the coiffure. The professional beauty operator usually administers the liquid as a spray. The ears, sides, and back of the neck are frequently covered with an appreciable amount of lacquer following this procedure. Other portions of the neck and face will be contaminated unless some protective measure is taken while the spray is being used. Many women have learned to apply the lacquer to their hair with an atomizer or with the finger tip.

It is therefore easy to understand why the ears, back and sides of the neck adjoining the hair margin, eyelids and forehead are the sites most commonly sensitized by hair lacquer. A dermatitis of the arms and forearms has been seen following the habit of resting the head on an arm during sleep.

Approximately four weeks ago a new method of application with special lacquer pads was introduced in this vicinity. During the last week 9 additional cases of hair lacquer dermatitis were proved to be due to the use of these pads. Women who had employed liquid hair lacquer for several years were attracted to this manner of application because of its simplicity.

Following a change to the frequent application of Huber lacquer pads, an incubation period of sensitivity of one to two weeks was observed before the dermatitis appeared. This incubation period was noticed in all patients who had used liquid hair lacquer for several years as well as those who had used it initially as lacquer pads. Patch tests with Huber lacquer pads, the brand employed by these patients, elicited positive reactions within twenty-four to forty-eight hours after sensitivity had developed. Patch tests to several brands of nail enamel in this group of patients sensitive to the liquid lacquer were uniformly negative. Contact tests to three different brands of liquid hair lacquer were also negative in this group.

¹ Downing, John G. Dermatitis Due to Ink Eradicator and Cosmetic Lacquers, Arch. Dermat. & Syph. 44: 465 (Sept.) 1941.

The principal chemical components of lacquer pads are reported to be two synthetic resins, 1 per cent caustic soda and 1½ per cent ammonia.

COMMENT

The sudden appearance of a large number of cases of hair lacquer dermatitis is comparable to the episode of resin finished underwear dermatitis observed some two years ago. At the time of writing 11 cases of hair lacquer dermatitis have been observed in our office. Fourteen similar cases were seen during the past two weeks by the other dermatologist in this city. This suggests that some new sensitizing material has recently been added to hair lacquer or lacquer pads. Lacquer pads were the offending agent in 23 of the 25 cases.

Most patients were found to be sensitive on patch test to only one brand of hair lacquer. This is contrary to the finding in nail polish dermatitis. When an individual is sensitive to one kind of nail polish he is usually allergic to all brands of nail enamel. An individual who is allergic to nail lacquer is not necessarily sensitive to hair lacquer. One example of dual sensitivity was observed.

ADDENDUM—Ten additional cases of lacquer dermatitis have been observed in our office since this paper was submitted for publication two weeks ago. Nine developed after the use of Hubere Lacquer Pads and one after Nutrine Lacquer was sprayed on the hair at a beauty parlor.

1719 Pacific Avenue

CONTACT DERMATITIS CAUSED BY HAIR
LACQUER PADS

A CHARACTERISTIC CLINICAL PICTURE

STEPHAN EPSTEIN, M.D. MARSHFIELD, WIS.

The 'up do' hair style has made it necessary to make more extensive use of lacquers than heretofore to keep the hair and locks in the desired position.

During the past few months hair lacquer pads have been introduced. They consist of powder puffs which are soaked with some form of lacquer. Beauty parlor operators and patients tell me that the lacquer of these pads is more "gluey" than the older fluids, which were usually sprayed on with an atomizer. For home use the pads provide a convenient means of application and are becoming more popular.

Recently I have seen several instances of contact dermatitis from this source. These cases presented a characteristic clinical picture. As there are—as far as I know—no reports of this form of dermatitis, it seems justifiable to call attention to its etiologic factor.

REPORT OF CASE

Mrs. T. H. and her two daughters, 4 and 6 years of age, were referred to me by their family physician on account of a puzzling symmetrical dermatitis of the face which had affected the three female members of the family about the same time. The clinical picture was strikingly similar in all three patients. The region of the ears and the adjacent areas over the parotid gland presented a more or less acute dermatitis. One of the girls exhibited considerable swelling which at first glance suggested a parotitis. On close inspection, however, the clinical picture was that of a typical contact dermatitis with redness, swelling, vesiculation and slight crusts. The mother had signs of a similar but milder eruption also on the back of her neck and on her forehead. Both she and one of the daughters had lately noticed a slight eruption on the inside of the right upper arm. During the following few days the dermatitis of the girls spread also to the face.

Questioning revealed the cause of this somewhat perplexing eruption. The mother who had an up do coiffure all around the head had used hair lacquer pads for about a month on several occasions. On Labor Day Mrs. H. had also applied pads to the temples of both girls in order to keep their hair in shape all day long. Seven and nine days later, respectively, the dermatitis appeared on the ears and cheeks of the girls.

Patch tests which have been carried out on the three affected members were positive about forty-eight hours after the application. The test was performed by touching a small area of

normal skin three times with a lacquer pad. No tape was applied. All three patients had a negative test to finger nail polish. The hair lacquer pads used in this case were manufactured by Hubere Cosmetics, Chicago.

COMMENT

The history and clinical appearance leave no doubt as to the relationship of the hair lacquer pads to the dermatitis. The location of the dermatitis corresponded exactly to the areas to which the pads had been applied. The incubation period of seven and nine days as observed in the girls demonstrates the allergic nature of the eruption. The discovery of the exciting factor was easy in this family eruption. It may be less apparent in isolated cases such as the following. A young woman presented a slight dermatitis of the back of the neck. She had used these pads only to hold some "stragglers" in line on the back of the head. Discontinuation of the use of the pads led to complete recovery within a short time.

The reported cases show that the use of these lacquer pads may produce a rather typical clinical picture, namely a symmetrical dermatitis of the ear and parotid areas. Irritation of sites distant from the application may also occur, for example, of the arms on which the patient's head may rest while asleep. In these respects it resembles nail polish dermatitis. It is furthermore noteworthy that all three female members of the family were affected and that one single application was sufficient to provoke a dermatitis in the girls. This indicates a highly sensitizing property of the pads. With their widespread use one might expect similar cases to occur not infrequently, especially among war workers who have to apply their make up in a hurry.

RESECTION OF THE LEFT VAGUS NERVE FOR
MULTIPLE INTRATHORACIC NEUROFIBROMAS

MAJOR BRIAN BLADES

Chief of Thoracic Surgical Section, Walter Reed General Hospital
AND

LIEUTENANT DAVID J. DUGAN

MEDICAL CORPS, ARMY OF THE UNITED STATES

Neoplasms arising from nerve tissue in the posterior mediastinum are rather common. Not infrequently neurofibromas in this location are associated with other stigmas of neurofibromatosis (von Recklinghausen's disease). The present case is in this category but was unique because the intrathoracic neurofibromas were multiple and involved both the left vagus nerve and the thoracic sympathetic nerves. Two of the tumor masses arose from and were part of the left vagus nerve and two neoplasms entirely separate from the others, arose from the posterior-superior sympathetic chain. All the tumors were removed successfully and microscopic sections revealed that their histologic characteristics were identical. In order to remove the tumors involving the vagus, it was necessary to resect 15 cm. of the nerve and it is noteworthy that no deleterious effects were noted following the resection of the nerve itself.

REPORT OF CASE

History—A well developed white soldier aged 35 had no signs or symptoms referable to the mediastinal tumor. The lesion was discovered during a routine examination when a roentgenogram of the chest was made. The physical examination was not significant except that café au lait spots were evident in both axillae and on the chest. This finding suggested strongly that the mediastinal tumor might be a neurofibroma. X-ray films of the chest revealed widening of the posterior-superior mediastinum. The trachea was not displaced. The widening was to the left of the midline and presented itself as one homogeneous mass. There was no clue from the x-ray examination that the tumors were multiple in character since the masses were superimposed in both the frontal and lateral projections on x-ray films (fig. 1). After all diagnostic pro-

From the Thoracic Surgical Section, Walter Reed General Hospital, Army Medical Center, Washington, D. C.

bilities had been exhausted including a test dose of roentgen therapy, surgical exploration of the thorax was recommended.

Operation.—Under intratracheal cyclopropane anesthesia an incision was made in the left posterior chest extending from the level of the fourth thoracic vertebra following the curve of the scapula and extending to the anterior axillary line (fig 2). The

Fig. 1—Homogeneous shadow in the posterior-superior portion of the left thorax.

underlying muscles were divided and the bony thoracic cage was exposed. The entire length of the fifth rib was resected subperiosteally and the underlying pleura opened. Rib-spreading retractors were inserted and the left pleural space was exposed. The left lung was free of adhesions and there was no evidence of tumor in it. In the posterior-superior sulcus of the thorax there was a pedunculated mass about 10 cm in diameter. The tumors

were beneath the parietal pleura. The pleura was incised and the tumors were dissected free without difficulty. It was evident that the origin of the neoplasms was from the sympathetic nerve trunk. The left side of the mediastinum had a lumpy appearance, and palpation revealed two tumor masses which were lying within the mediastinum beneath the mediastinal pleura. Accordingly the mediastinal pleura was opened and two egg-shaped masses, each about 5 cm in diameter, were identified and isolated. These tumors originated in the left vagus nerve and were obviously neurogenic in origin. The left recurrent laryngeal nerve was identified and saved. The

Fig. 2—Incision employed for exposure of the mediastinum and left pleural cavity.

left vagus and the two tumors were dissected free from the vagal plexus about the hilus of the left lung and about 15 cm of the nerve was exposed. After the tumors and the nerve were isolated from the other structures in the mediastinum, the two neoplasms and the involved portions of the left vagus were removed (fig 3). One mass was just below the arch of the aorta, the second and interior mass in the vagus was

at the level of the left pulmonary hilus. The mediastinal pleura was closed. 10 Gm of sulfanilamide crystals was placed in the pleural space and the chest wall was reconstructed in layers. The wound was closed without drainage. There were no changes in respiratory rate, blood pressure or pulse noted during the resection of the segment of the vagus nerve or at any time during the operation.

Postoperative Course.—This was uneventful. At no time was there evidence of shock. Pulse rate, respirations and blood pressure remained within normal limits. Three hundred cc of bloody fluid was removed from the left pleura on the second postoperative day. The patient was out of bed and eating free from symptoms fourteen days after the operation.

A transient cervical sympathetic paralysis (Horner's syndrome) appeared as a result of manipulations of the sympathetic nerves, and paralysis of the left vocal cord became evident.

These effects were attributed to edema caused by manipulation of the nerves during the dissection. Immediately after the operation, during the routine postoperative bronchoscope examination the vocal cords were visualized and moved normally. Paralysis of the left vocal cord became evident on the second postoperative day, and normal function did not return for two weeks.

COMMENT

A case of perineural fibrosarcoma of the left vagus nerve has been reported by Furrer and Fox.¹ The lesion was uncovered at postmortem examination. We have not been able

Fig. 3—Tumors. A—two tumors of the left vagus nerve resected. B—two tumors of the vagus between the two neurofibromas. C—two tumors originating in the posterior-superior sympathetic nerve.

to find a recorded case of a primary nerve tumor of the vagus nerve subjected to operation. The sympathetic nerve is a frequent site of origin of neurogenic tumors, but involvement of both the sympathetic and parasympathetic nerve trunks in the same patient with surgical removal has not been described.

The necessity of resecting a large part of the vagus nerve was not considered a serious handicap to the patient. The operation was performed. Since the recurrent laryngeal nerve could be saved, it was anticipated that no serious physical effects would be manifested after the removal of the remaining portion of the left vagus in the thorax. This proved to be the case. Experiences during the performance of total parathyroidectomy, resection of the thoracic esophagus and other thoracic procedures where accidental or deliberate division of the vagus may occur have furnished convincing clinical evidence that the interruption of one vagus nerve in the thorax is of little consequence. Moreover, it seemed logical to assume that in our case function of the left vagus had already been altered or destroyed by the two large tumors of the thorax.

It is generally recognized that primary nerve tumors of the mediastinum have a definite tendency to become malignant. There was no hesitation therefore to excise a sufficient length of the involved nerve trunk to insure removal of the tumors. The soldier is now on duty.

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
AUSTIN I. SMITH, M.D., Secretary

THE LOCAL USE OF SULFONAMIDE COMPOUNDS IN DERMATOLOGY

HAROLD N. COLL, M.D.
CLEVELAND

HISTORICAL

Domagk,¹ working in the experimental laboratory of the I. G. Farben Industrie Elbertfeld, in 1935 reported that a compound (4-sulfamido-2',4'-diamino-benzene hydrochloric acid), which he called prontosis, acted favorably on hemolytic streptococcus infections in mice. For this he was granted the Nobel prize, which the German government denied him accepting. At the May 17, 1933 meeting of the Dusseldorf Dermatologic Society Schreus,² from his dermatologic clinic at Dusseldorf, reported that a boy aged 1½ years suffering from an apparently fatal staphylococcal infection had been given 0.05 Gm of prontosis twice a day. In four days the temperature fell to normal. The medication was continued for several weeks with short intervals of rest and the boy was well. Schreus stated that the I. G. Farben Industrie had sent him some of the compound to try out.

Sulfanilamide had been synthesized in 1908, though nobody paid any attention to it medically for years. Schnitker³ points out that in 1909 some of the first azo dyes were prepared with sulfanilamide and substituted sulfonamide groups. One of these, chrysoidin (2',4'-diamino benzene) was used in the dye industry for years. Then it was found that these dyes had a bactericidal effect in mice and it was suggested as a chemotherapeutic agent. In 1932 there was synthesized a derivative of chrysoidin in the form of a hydrochloride of 4-sulfamido-2',4'-diamino benzene. It was this derivative of chrysoidin that Domagk called prontosis and which was the original effective dye substance. It is converted into sulfanilamide in the human body. It is not used in the United States. Neoprontosis is the disodium salt of prontosis and is known also as prontosis soluble and prontosis solution. Since then many of these derivatives of the prontosis have been worked out and tried clinically, but, as Long⁴ puts it, "Knowledge concerning optimal doses and the fate of the prontosis in the human body lags behind that which is known for sulfanilamide." This compound is known as prontosis album in Germany.

In the United States the Council on Pharmacy and Chemistry early recognized the significance of the sulfonamides. And, moreover, in view of the multiplicity of these preparations and of names, the Council

attempted to exercise discretion and conservatism in accepting, under a careful system of nomenclature, those compounds which seemed to be of the greatest therapeutic value in terms of lowest toxicity. Thus was avoided the deplorable confusion in sulfonamide nomenclature such as is seen in Europe today, here in contrast the compounds are known by single names. The following compounds have thus far been accepted for N. N. R. sulfanilamide, sulfathiazole, sulfapyridine, sulfaguanidine, sulfadiazine, succinylsulfathiazole and the sodium salts of sulfapyridine, sulfathiazole and sulfadiazine.

LOCAL USE OF SULFONAMIDES

These preparations were first used orally for the treatment of infections and it was only later that their external use was suggested. As in the case of many other potent drugs, this employment has often been abused and many times they have been tried where there was no indication for their use. Nevertheless there are certain dermatologic infections in which sulfonamides are not only helpful but definitely of value. Thus as early as 1938 Baccaredda⁵ pointed out that local applications of sulfanilamide were often more active than other methods of antiseptics. He also considered the drug well tolerated and he observed no resultant dermatitis medicamentosa. Lam⁶ in 1940 reported his experiences with sulfanilamide used locally. Sulfanilamide is soluble only to 0.8 per cent in water but much more so in glycerin and alcohol. He employed a supersaturated solution in glycerin in all cases of impetigo, acute infectious folliculitis, septic ulcers and other streptococcal and staphylococcal infections. MacKenna⁷ successfully treated impetigo and ecthyma by dusting a fine powder containing sulfapyridine on the lesions and then covering them with zinc paste and a tight dressing. Spink,⁸ in reporting the successful local use of sulfathiazole in a group of staphylococcal wounds and ulcers emphasized the necessity for debridement and the freeing of the lesions from purulent and necrotic material before making the applications. Combes and Canizares⁹ treated a few cases of impetigo with 10 per cent of sulfanilamide in olive oil and hydrous wool fat. The cases responded in four to seven days. Several chancroidal infections were cured by the use of sulfanilamide powder. Hrad¹⁰ worked with albucid (acetylsulfanilamide) and prontosis (4-sulfamido-2',4'-diamino-azo-benzene). With ointments alone the results were good in pyodermas and impetigo. He found that bases, water soluble in type, gave better results. In certain of the cases concomitant internal use of the compound also was found helpful.

Schneider¹¹ at Ramel's clinic at Lausanne tried various sulfonamides in impetigo, perleche, ecthyma, impetiginous eczema, secondarily infected dermatoses

occupational in type and retroauricular dermatitis. He used prontosil soluble in aqueous solution (disodium 4 sulfamidophenyl-2'-azo-7'-acetylamino-1'-hydroxy naphthalene-3',6'-disulfonate), also known as azosulfamide and prontosil red (known in France as rubiazol, the chemical formula of which Long tells us has been changed at least once), ultron (sulfamid-dimethyl-sulfanilamide) and then sulfapyridine. With the last they had excellent results though occasionally local intolerance developed. Then he tried sulfamidothiazole (sulfathiazole), which was better tolerated and had the advantage of the thiazole group against the staphylococcus. They treated 124 cases including secondary furunculosis, infected acne vulgaris folliculitis, anthrax, mycoses ulcers of the legs and psoriasiform parakeratoses. Naturally, results were not so good in the last group of cases.

Pillsbury, Wammock, Livingood and Nichols¹² treated 190 cases of infections of the skin. In 137 of them in which pyogenic infection was partially or solely the cause, results with sulfathiazole ointment in an oil in water emulsion were excellent. The authors tried sulfanilamide, sodium sulfadiazine and sulfathiazole. The last was relatively effective in staphylococcal and streptococcal infections. They mentioned the greater solubility of the sodium salts of these drugs, but also their higher pH .

Keeney, Pembroke, Chataud and Ziegler¹³ reported good results from 5 per cent of sulfathiazole in a base of hydrous wool fat and vanishing cream. They also used a 5 per cent sodium sulfathiazole ointment and noted no difference in their results. They treated 16 infected eczemas in children. In 1 case they used the compound three times a day, bringing the infection under control in forty-eight to seventy-two hours. There was no effect on the eczema. The infant was then put back on liquor carbonis detergens ointment and became reinfected. They then put the sulfathiazole in the liquor carbonis detergens ointment with good results. They also had favorable effects in infected varicose eczema, seborrheic dermatitis of the scalp and concomitant involvement of the external auditory canal. Ten children with impetigo of the face and scalp and two of the torso as well were better in forty-eight hours and cured in seven days. An adult with furunculosis of the thighs was treated with sulfathiazole ointment applied to the lesions and adjacent skin three times a day, there was no further spread, and the furuncles gradually cleared up.

The Robinsons¹⁴ found sulfathiazole ointment superior to ammoniated mercury ointment in the treatment of pyodermas, impetigo, ecthyma and paronychia. Results were not so striking in sycosis vulgaris. Two chancroidal infections responded nicely. Twenty-six patients in whom the primary condition was coccogenic responded nicely and in secondary pyogenic infection the complicating infection cleared up. The drug was of no value for dermatophytosis per se, granuloma inguinale, uncomplicated contact dermatitis and dermatitis herpetiformis.

Abramowitz¹⁵ likewise agrees that the sulfonamides are valueless in uncomplicated mycotic infections. He even feels that they should not be used in impetigo and minor infections of the skin unless ordinary measures fail.

Miller¹⁶ treated 115 cases of various skin infections with sulfanilamide, sulfathiazole, sodium sulfathiazole and sulfadiazine. The preparations, varying in strength from 5 to 50 per cent, were incorporated in two different bases, essentially water in oil emulsions. The drugs were in a suspended state, the size of the suspension approaching the colloidal state. The effects of the drug were checked by cultures on blood agar plates.

There were 45 cases of impetigo which were cured in three to ten days. In 14, white precipitate ointment and in 7 gentian violet had previously been employed. It was his custom to employ hot boric acid compresses followed by the selected ointment twice a day. The results from sulfadiazine were not as good as from sulfanilamide and sulfathiazole. In 12 cases of ecthyma cure took place within ten to twenty-five days. The results in 12 cases of sycosis vulgaris were not so gratifying. Three were cured in one month, in 1, sensitization to sulfathiazole occurred in the process. It had no effect on dermatitis repens, and 1 of 2 cases of folliculitis was cured. In secondarily infected infantile eczema, chronic recalcitrant dermatitis of the fingers, allergic eczema and mycotic infections, the infection cleared up but not the basic trouble. In epidermolysis bullosa, psoriasis, pustular acne, seborrheic dermatitis and pustular bacterid there was no result. The author advised against use of high concentrations of the drug for fear of sensitizing patients. He found that sodium sulfathiazole showed no greater efficiency and, because of its greater alkalinity, was more likely to produce irritation.

Kalz and Prinz¹⁷ think that sulfanilamide and sulfathiazole are more suitable than sulfapyridine for treatment of skin disorders because of their greater solubility. The sodium salts are soluble even up to 30 per cent but they are also very alkaline with a pH even up to 10 to 13. With ointments used in 2 to 10 per cent strength and with poor solubility of the compounds they think it must be difficult to achieve a sufficient tissue level by a concentration lower than 5 per cent in the vehicle. They do not like petrolatum as a base—it does not mix with serum and it coats the particles with a nonsoluble substance. The solubility of sulfathiazole in glycerin is ten times that in water at room temperature. Kalz and Prinz used 30 per cent of sulfanilamide and sulfathiazole suspended by emulsifying agents in glycerin. The resultant cream was miscible with water and serum. It was white, soft, with a pH between 6 and 7 and when applied to the skin formed an elastic half dry adherent coating. After some experimenting with these two compounds in 15 cases they used sulfathiazole exclusively. It was superior in its effects, the crystals of sulfanilamide were very hard, gritty and irritating. Moreover, with sulfanilamide the resultant blood level in infants was higher, which they considered unfavorable. They treated a

total of 130 cases with their sulfathiazole glycerin paste and of 107 superficial infections, 99 were cured within fourteen days. The preparation was valuable in impetigo and ecthyma cures occurring in seven days. It also was effective in infected dermatoses and dermatophytosis. Later the mycotic infection could be handled with other measures as sulfathiazole is not fungicidal. Acute cases of syphilis vulgaris reacted better than chronic ones. In infectious eczematoid dermatitis the results were doubtful.

Very recently Harris¹⁸ in reviewing the entire subject of treatment of impetigo by the sulfonamides, has called attention to a new physical form of the sulfonamides named "microcrystalline" by Chambers¹⁹ who first prepared the microcrystals at the University of Pennsylvania. A number of the commonly used sulfonamides in this form have been prepared by the Smith, Kline and French Laboratory Philadelphia. Harris used a 20 per cent microcrystalline sulfathiazole. A drop or two of the suspension was poured out on a small gauze dressing. The area to be treated was carefully washed with soap and water with removal of all the crusts. If necessary the area was shaved. The gauze dressing was then applied to the area the bit of sulfathiazole paste being placed in contact with the lesion. On removal of the dressing twenty-four hours later the impetigo was always healed. Fifteen children with a total of 293 lesions were thus treated and 290 of the 293 gave identical results. In 3 lesions treatment for another day or two was employed. In no case did a lesion recur or new areas develop. I have found these compounds to be invaluable in treating impetigo and ecthyma.

Greenblatt²⁰ reports excellent results from vaginal insufflation with sulfathiazole or sulfadiazine powder in the treatment of Trichomonas infection. He used a powder containing sulfathiazole 1 part and beta lactose 3 parts. Eight Gm of the mixture was insufflated daily for four treatments. Flagellates lost their motility in ten to fifteen hours. Blood sulfathiazole levels were not raised to dangerous levels, which is quite understandable as 2 Gm of the drug daily would not be a large dose.

There is one local infection for which powdered sulfonamides appear to be practically a specific—chancroidal infection. Combes and Canzares used 80 per cent of sulfanilamide and 20 per cent of starch. Lepiny²¹ employs the foregoing or the pure sulfanilamide powder dusted on the ulcer alone. Many other investigators have also noted the beneficial effect not only of sulfonamides internally in chancroidal infection but also the almost miraculous effect of their local use. We thoroughly endorse the use of these compounds for Hemophilus ducreyi infection. It is the custom in the Cleveland City and University Hospital dermatology and syphilology services to cleanse the ulcers carefully and dust them with either sulfanilamide or sulfathiazole. The powder readily adheres to the open ulcer and literally seals it. In fact, it is rather difficult to

remove it. Care should be exercised to put the powder on the ulcer only. It may be soaked off and replaced daily or every other day. Usually the ulcer heals within a matter of a week. If there is extensive ulceration with concomitant bubo formation, simultaneous therapy by mouth is in order.

MODE OF ACTION OF SULFONAMIDES

An editorial²² in the London *Lancet* stated that the sulfonamides had a local bacteriostatic action, further, that they occasion no interference with the healing processes of phagocytosis, leukocytic infiltration and the formation of granulation tissue even with the high local concentration of the drugs. The opinion was expressed that powdered sulfathiazole was more potent against streptococci and pneumococci and even influenced staphylococci—more than sulfanilamide and sulfapyridine. Schmitz in his careful review of the whole subject says their local use allows a high concentration to act bacteriostatically and bactericidally. Keefer²³ thinks sulfanilamide is a bacteriostatic agent. It stimulates phagocytosis. It alters organisms so that phagocytosis can take place.

On the other hand, Veal and Klepser²⁴ think the continued use of pure sulfanilamide retards the growth of granulation tissue. They state that there are no toxic reactions, that sulfanilamide when instilled into pyogenic wounds, acts locally by inhibiting growth of certain organisms chiefly the streptococcus, staphylococcus colon group and *Pseudomonas aeruginosa* (*Bacillus pyocyaneus*). Bick²⁵ thinks that local applications of sulfonamide drugs to normal and soft tissues in a cleancut operative incision in which primary suture is indicated retards healing at least 50 per cent and may promote excessive scarring. However, its use is almost obligatory in cases in which infection may be anticipated such as in contaminated wounds under field conditions.

Hawking²⁶ showed that when 0.2 Gm of sulfanilamide was inserted into an experimental wound of the thigh in a guinea pig it was absorbed and disappeared in less than twenty-four hours. With sulfapyridine this took seven to ten days and with sulfathiazole four to five days. He also studied the absorption of sulfonamides in tubular wounds in the back of rats. Sulfanilamide will travel from the central cavity of the wound down into crevices. It will slowly penetrate into fragments of dead tissue, by local action it will not penetrate far into tissue with intact circulation. The best compound to use is sulfanilamide. It is cheaper and has a high local concentration, greater power of concentration and diffusibility. It disappears rapidly and has lower bacteriostasis. Sulfathiazole persists longer and has a higher bacteriostasis but lower concentration and diffusibility. Sulfapyridine has no advantage as compared to sulfathiazole and has the disadvantage of still lower concentration.

But how do these various sulfonamide compounds act in the clearing up of infection? Mention has already been made of their bacteriostatic and bactericidal effect.

DOES THE UNITED STATES NEED A MEDICAL REVOLUTION?

THE WAGNER-MURRAY-DINGELL BILL I

The Wagner-Murray-Dingell Bill proposes a complete revolution of medical practice in the United States. Nearly every institution concerned in the prevention, diagnosis and treatment of disease would have to modify its method of rendering service. The type of medical education and research and the administration of hospitals would be grossly altered. The immediate results of revolution are almost always destructive. For several years the institutions that protect and maintain the health of the American citizens would certainly be so disrupted as to make the efficient performance of their functions for the protection of the health of the American people almost impossible.

Is our situation today so desperate as to call for so radical a remedy? Medicine never hesitates to use radical measures when required in desperate situations. Do present conditions indicate defeat in the battle against death and disease? The reverse is true, according to reliable vital statistics. Never was the general death rate lower or falling more rapidly in relation to all the conditions that affect that rate than now. The infant death rate, accepted throughout the world as the most accurate measure of public health, is lower in the United States today than in almost any other country in the world. Although this decline has continued for many years and therefore might be expected to be approaching a minimum, it has shown an accelerated fall in recent years. Life expectation is greater here than in almost any other country and definitely longer than in any having systems of compulsory sickness insurance. The recent phenomenally rapid increase in the birth rate in recent years, which has always hitherto been accompanied by an increase in maternal infant death rates, has been accompanied by a decline in these rates in the United States.

The public health movement is certainly not declining in scope or efficiency. Public health departments, which almost invariably owe their origin and protection from

the corrupting influence of politics to the activity of physicians either singly or in organizations, have now attained a momentum which is carrying their work into every community. The constant watchfulness of the medical profession has secured the administration of increasing numbers of these departments by competent trained personnel and strengthened their power to protect the public against disease.

The claim that American hospitals are in general best equipped of any in the world cannot be challenged. They are the models admired by other nations. Medical education, which at the beginning of the century was considered in many of its aspects disgraceful, has, thanks almost exclusively to the active supervision of the medical profession in the United States, attained world leadership.

These are not the conditions that call for revolutionary activity. Every phase of medical development in this country testifies to the soundness of the progress that has been made and indicates the desirability of continuing evolution.

The United States gained its leadership in medical education and care by methods that have been tested in the crucibles of time and economic hardship. Now it is proposed to abolish these institutions and methods and to substitute others whose trial in many countries has failed to produce health conditions equal to those existing here. The Wagner-Murray-Dingell Bill would abolish the volunteer control and inspiration that have brought medical education, hospital management, drug purity, research and medical service to their present eminence. As a substitute the people are offered a system controlled by salaried political bureaucrats. Scientists have too many aphorisms warning against such "ersatz" to participate in destroying what they have found good.

PREFRONTAL LOBOTOMY

Prefrontal lobotomy, surgical division of the central core of the white matter within the frontal lobes, is empirically designed to sever the connections of the frontal cortex and especially to interrupt the projections which connect the frontal regions with the thalamus and hypothalamus. The consensus is that the frontal lobes are concerned with imagination, the social sense, self consciousness and similar mental activities. While the frontal lobes are important for the psychic life of man, the concept of psychic centers similar to those for vision, for motor control of the limbs and for speech has not been established. Moniz¹ believes that certain cortical areas associated with other areas in the diencephalon and metencephalon correspond to certain psychic manifestations. Apparently loss of one frontal lobe can be functionally replaced by the activity of the other. In man one frontal lobe can be extirpated without producing psychic changes. In a case described by

¹ Moniz, Egas. Les premières tentatives opératoires de traitement de certaines psychoses. *Encephale* 2:1 (June) 1936.

Brickner² both frontal lobes were removed because of the presence of a meningioma. Psychic disturbances resulted including impairment of memory particularly loss of memory for recent events and loss of control of the emotions. Spurling³ states that there was no definite permanent defect produced in the intellectual status of a patient whom he studied by removing the entire right prefrontal lobe even though there had occurred previously partial destruction of the left prefrontal area.

In the insane there are fixed morbid complexes to which all other activity is subordinated, these are related to cellular aggregations which appear to be fixed. Moniz proposed to treat such patients by destroying these cellular interrelations, particularly their connections with the frontal lobes.

In this country Watts and Freeman⁴ have apparently had the most extensive experience with the operation. They have reported 136 instances of bilateral prefrontal lobotomy. Anatomic studies of their patients who died some time after the operation showed that there is integrity of the cortical architecture in the frontal lobe but that degeneration occurs in the nucleus medialis dorsalis of the thalamus. They believe that this bundle is of importance in linking ideational with affective experience and that interruption of this pathway is the greatest factor in producing alteration in emotional responses of the patient. They performed the operation under local anesthesia and state that little shock was associated with it. In their experience the patient who has undergone prefrontal lobotomy is friendly, cheerful, agreeable, relaxed and interested in what goes on about him, he is always ready for the next meal and never complains of indigestion, nor does he worry about heart disease or any other malady, he sleeps soundly and without dreams, sometimes he is mentally indolent, at other times he seems oblivious to sensations of fatigue, he is a procrastinator, he likes to spend money when he has any but gets along just as well when he has none, he is able to worry, but more about externals than about himself, he is a complete extrovert. Their best results were obtained in the obsessive tension states and in the involutional depressions.

In a panel discussion⁵ held at the Cleveland session of the American Medical Association those who participated agreed that the operation produces a defect and that this defect cannot be easily tested by the ordinary formal tests of intelligence. It was also felt that delimitations of the usefulness of the operation have

not been clarified. The editorial comment⁶ in *THE JOURNAL*, while not condemning the procedure, asserted that more scientific evidence will be required before the operation can be regarded as a worthwhile procedure.

In a recent symposium by English authors Rees⁷ stated that the operation is indicated for the relief of such symptoms as anxiety, apprehension, self mutilation, suicidal tendencies, destructiveness, attacks of violence and states of tension which may be found in many forms of psychosis or psychoneurosis. Patients best suited for prefrontal lobotomy are those with functional mental disorder who have symptoms of active conflict and have failed to respond to other methods of treatment and in whom the prospects of spontaneous recovery are remote. Knight⁸ performed prefrontal lobotomies on 30 patients with mental disorder and noted the disappearance or lessening of depression in 4 out of 7 with melancholia, improvement in conduct and behavior of the 16 remaining patients and the improved quality and output of work of 13. Among the undesirable results were loss of initiative and spontaneity, persistence of delusions or hallucinations and development of emotional lability or euphoria, retardation, irritability, aggressiveness and volubility. The more physical sequelae included loss of sphincter control, development of voracious appetite, trophic disturbances and occurrence of epileptiform fits. Fleming and McKissock⁹ reported the results of prefrontal lobotomy on 15 patients. Of the 12 patients with melancholia 7 have made complete recovery and 1 has shown considerable improvement, but the other 4 have shown little improvement. Hutton¹⁰ reported the results obtained with 50 patients subjected to prefrontal lobotomy, the mortality was 4 per cent. One patient died of cerebral hemorrhage caused by section of the anterior cerebral artery. No patient was reported as being worse after the treatment than before. Hutton emphasizes that rehabilitation after the operation is of utmost importance. Personal attention and encouragement are necessary, and when these are lacking the results tend to be disappointing. The greatest success is obtained with patients of good intelligence whose relatives have sufficient interest, affection and understanding to help in the process of reeducation. Golla¹¹ states that the lack of prevision in these patients (postoperatively) is related to the forethought necessary to appreciate the situation of the self in relation to the environment. The patients become careless because they no longer seem to appreciate their social obligations or to pay

much attention to their relations with others. The mortality rate from the operation ranges from zero in Lyster's¹² series of 55 cases to 22 per cent in the series of Watts and Freeman and 4 per cent in the series reported by McKissock.¹³ The most important immediate complication is cerebral hemorrhage. Epileptic convulsions as a remote sequela developed in 8 per cent of McKissock's series and in 10 per cent of Watts and Freeman's. In this series also there was 1 case of permanent hemiplegia. Watts and Freeman believe that the operation gives more permanent results than shock therapy. Strom-Olsen¹⁴ expressed the belief on the basis of 30 personal cases that certain disturbing mental symptoms may be alleviated by this operation in about one half the total number treated."

Prefrontal lobotomy on the basis of the experiences here cited, would appear to be beneficial in some types of psychotic patients in whom all other methods of treatment have failed and when chances of remission or recovery are remote.

FOOD RATIONING FOR INVALIDS

Elsewhere in this issue (page 422) appears a report made by the Subcommittee on Medical Food Requirements of the Committee on Drugs and Medical Supplies of the Division of Medical Sciences of the National Research Council to the War Food Administration relative to the recommended allowances of certain types of foods for invalids in various categories. The subcommittee contains in its membership representatives of the various sections of the American Medical Association and of special societies in the field of diabetes hospitals and similar agencies which are greatly concerned with these matters.

The regulation of the distribution of essential foods during war is one of the most difficult problems that have confronted governmental agencies. From available information it is clear that physicians in certain areas have not hesitated to recommend for certain types of disease large amounts of food substances entirely without relationship to the scientific criteria that should prevail in matters of this sort. Since the local rationing boards are, in most instances, not equipped by virtue of the knowledge of their members or in any other way to decide matters of this kind, the requests of patients accompanied by the certificates of physicians have in many instances been granted. While the total amount of food lost in this way has not been great, the damage to public morale in unwarranted dissipation of necessary food materials has been considerable.

As a part of the report of the special subcommittee there appear also two recommended forms to be used

by patients and physicians in making their needs known to the local rationing boards. No doubt the Office of Price Administration will extend the important information here supplied to the local rationing boards so that they may be guided by the advice of this authoritative group in making their allowances to invalids who may require extra amounts of important food substances. The mechanism of administration provides for appeals from the decisions of local rationing boards to regional offices and indeed from the regional offices also to the national office. In many instances regional boards have themselves established advisory bodies of physicians to aid them in making decisions on such appeals as might come to them.

Current Comment

FEDERAL FUNDS FOR RELOCATION OF PHYSICIANS

The President has transmitted to the Speaker of the House of Representatives supplemental estimates for the Public Health Service amounting to \$4,427,550. Of this sum \$2,350,000 will be used, it is proposed, for an extended program of malaria control for the United States' share of a joint Anglo-American venereal disease control program for the protection of soldiers stationed in the Caribbean area "and for the supplying by the Public Health Service on request of state authorities, of needed medical and dental care, either by temporary financial aid or by direct employment of doctors and dentists, in certain critical areas where acute shortages have developed which cannot be met without recourse to emergency measures." The transmitted estimates, pending in the House Committee on Appropriations, contain the following provision:

Provided, That the Surgeon General is authorized, on request of a state health department (1) to assign medical and dental personnel of the Public Health Service to areas found to be in critical need of additional medical and dental services, such services to be furnished the public in accordance with schedules of fees approved by the state health departments and the Surgeon General of the United States, which fees shall be collected by, and used at the direction of, the state departments of health, to defray the expenses thereof incident to the rendition of such medical and dental services, the balances at the end of the fiscal year to be covered into the treasury as miscellaneous receipts, and (2) to enter into agreements with private practicing physicians and dentists under which, in consideration of the payment to them of a relocation allowance of not to exceed \$250 per month for three months and the actual cost of travel and transportation of the physician or dentist and his family and household effects to the new location, such physician or dentist will agree to move to and engage in the practice of his profession in such area for a period of not less than one year.

Strictly as a war measure the technique proposed may be the only possible answer to the needs of certain areas in the United States which are now without medical service. The appropriation is to be used for this purpose only for the present fiscal year. Whether or not physicians can easily be found to meet this need, whether or not the time has come to discuss

¹² Lyster, J. G. in discussion on Watts and Freeman.
¹³ McKissock, Wylie. The Technic of Prefrontal Leukotomy, J Ment Sc 89 194 (April) 1943.
¹⁴ Strom-Olsen, R., List, S. L., Brody, M. B., and Knight, G. C. Results of Prefrontal Leukotomy in Thirty Cases of Mental Disorder, J Ment Sc 89 165 (April) 1943.

mechanisms thus far prevailing in meeting this need, whether or not state health departments can be helpful in assuming this function, are questions which remain to be answered if the Congress makes the appropriation

INFORMATION

Under the heading of Medicine and the War in this issue of *THE JOURNAL* appears the announcement of a grant of funds made available by the Johnson and Johnson Research Foundation to the Division of Medical Sciences of the National Research Council to be used in collecting and disseminating information regarding advances in medical science. There is in medicine a cultural lag as there is in every other phase of human activity. The time required from the development of an important advance in the field of medicine to the moment when it becomes the property of workers in the field is, in most instances far too long. Anywhere from a year to ten or a dozen years may elapse before a new discovery is so widely disseminated as to be generally applicable in the care of the sick. Particularly in wartime does the cultural lag become significant. Physicians actively engaged in military services are unable to devote the necessary time to the acquiring of information and to its transmission. For instance, the treatment of burns and the treatment of wounds vary not only among the armed forces of the various nations engaged in war but even among various branches of the armed forces of the same nation and also perhaps among various agencies of the Army, Navy, Air Force or similar groups. The grant made available by the Johnson and Johnson foundation will permit not only the collection and dissemination of individual reports coming from all the world regarding certain phases of medical service but also the sending of actual observers for the collection of complete information regarding any special problem of medical care of national or worldwide importance. Already many medical leaders have reflected the view that there will be in the postwar period a dissemination to the United States of conditions previously seen only in the tropics and about which American medicine is not yet fully informed. A series of reports on such conditions based on immediate first hand study will be of great service in the control of such diseases. Another project of the Committee on Information of the Division of Medical Sciences of the National Research Council is the compilation and publication of a history of medicine in this war. Through the subcommittee under the chairmanship of Dr. John F. Fulton, which has this work in charge, there is being collected a vast storehouse of information becoming available throughout the world. The work has been outlined, and editors, special editors and authors have been appointed for the various sections. Much of the material that will be collected under the auspices of the new grant will become available for ultimate inclusion in this important historical contribution. The contribution of the Johnson and Johnson foundation thus becomes of the greatest significance for medical progress.

RHEUMATIC FEVER IN CHILDREN

Rheumatic fever according to the Bureau of the Census reports, is responsible for more deaths of children from 5 to 14 years of age than any other cause and accounts for a large number of deaths in older age groups as well. The appropriation of federal funds for services for crippled children under the Social Security Act of 1935 has been extended to include aid to state agencies for the development of services for children affected with rheumatic fever.¹ At present fourteen states have programs in operation for the care of children with rheumatic fever or heart disease, five others are reported intending to submit plans for rheumatic fever programs during the fiscal year of 1943, at least ten additional states have informed the Children's Bureau of their interest in such a program. The program includes education of parents in recognition of early symptoms, provision of hospital facilities and convalescent wards, public health nurses for home visiting and like measures. Accurate evaluations of the practical results of these measures have as yet appeared. If it can be demonstrated that the incidence of rheumatic fever can be reduced and the crippling effects mitigated, rapid extension of the effective features of the program should be encouraged.

EGG CULTURE METHOD IN ETIOLOGIC DIAGNOSIS OF MENINGITIS

The chick embryo is a good medium for culture of bacteria and other microbes. Blattner and his associates¹ have obtained favorable results with that medium in the diagnosis of acute meningitis. At times the older cultural methods yield negative results in meningitis even when smears of the spinal fluid reveal the presence of bacteria. The failure of bacteria to grow under these conditions may be due to the method used or to the state of the bacteria themselves. In 52 cases of acute meningitis Blattner and his associates failed to obtain bacteria in cultures on agar mediums in 8 per cent and on egg medium in only 2 per cent. Of these 52 cases 39 were due to meningococci which were obtained in culture in all but 1 case, in 3 cases blood agar culture remained sterile but the egg cultures were positive, and in 14 cases meningococci were obtained in egg cultures twenty-four to eighty-seven hours before any growth had developed on agar. Analogous results were obtained in pneumococcal and influenzal meningitis. In pneumococcal meningitis prompt isolation and typing are important in order that proper treatment may be given with the least delay. The egg method is of great value in the prompt identification of the bacterial cause in meningitis, especially when the smear of the spinal fluid reveals no bacteria or doubtful forms. That viable organisms may persist in spinal fluid apparently sterile on the older agar mediums, lends support to the continuation of chemotherapy after the apparent clinical cure of the patient.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession

FOOD RATIONING IN WARTIME

RECOMMENDATIONS OF THE NATIONAL RESEARCH COUNCIL

With the inauguration of a point system of rationing on March 1, 1943 the Office of Price Administration became the administrative agency, and the public's traditional peacetime latitude of dietary choice, limited only by ability to pay, was abruptly curtailed. As point rationing was extended to include a broad range of meats, fats and processed foods, it became evident that certain institutions and certain groups of the population would, because of special dietary needs, require special consideration. Prominent among these were hospitals and those sick individuals whose illness demands rationed foods in amounts greater than that provided by their "points." On the Food Distribution Administration of the Department of Agriculture developed responsibility for the equitable distribution of food and therefore responsibility for assuring the needs of the sick and of institutions caring for the sick.

Furthermore, it was recognized that in recent years great advances have been made in the understanding of the vital role that dietary components play in the body economy under conditions of health, stress, disease and convalescence. The role of these components can be evaluated with increasing precision in the light of modern nutritional research. Therefore in April 1943, at the request of Mr. Roy Hendrickson, director of the War Food Administration, Dr. Ross G. Harrison, chairman of the National Research Council, appointed a group of nationally known physicians to advise the War Food Administration concerning the extent of these special needs and the best method of meeting them.

Within the Division of Medical Sciences of the council this group was organized as the Subcommittee on Medical Food Requirements under the general jurisdiction of the Committee on Drugs and Medical Supplies, of which Dr. Walter W. Palmer of Columbia University is chairman. The subcommittee was composed of physicians representing various fields of medicine and consisted of Dr. William Stroud, Philadelphia, chairman, Dr. Cecil Striker, Cincinnati, Dr. Alton Ochsner, New Orleans, Dr. C. W. Munger, New York, Dr. Clark Finnerud, Chicago, Dr. Gilbert Levy, Memphis, and Dr. Walter W. Palmer (ex officio), New York. A first meeting was held in Washington on April 30 and May 1 at which the broad outlines of the problems involved were reviewed and discussed. At this and at subsequent meetings, representatives of the Civilian Food Requirements Branch, War Food Administration, and of the Food Rationing Division, Office of Price Administration, were present to acquaint the subcommittee with administrative aspects of the rationing program. Other committees of the National Research Council were called in consultation, notably the Committee on Surgery and the Subcommittee on Tuberculosis. The opinions of individual specialists in certain fields of medicine were solicited. Finally all recommendations of the subcommittee were reviewed and approved by the parent Committee on Drugs and Medical Supplies before transmission to the War Food Administration.

PRECEDENT

In the Food Rationing (Special Diets) Advisory Committee of the British Medical Research Council, the National Research Council's Subcommittee on Medical Food Requirements has had precedent. The British committee acts in an advisory capacity to the Ministry of Food, which implements its recommendations. Maximum allowances of extra rations have been formulated for a specific list of qualifying diseases. Likewise diseases and con-

ditions qualifying for priority claims on milk and eggs have been designated, and provision is made for the consideration of appeals for extra rations under circumstances not already stipulated. The British program has worked well and abuses have been minimized by requiring that the certifying physician provide strict medical evidence for most of the illnesses specified. Authority for certification of patients has been exclusively limited to licensed practitioners of medicine.

However, there are outstanding differences in the British supply position and that of the United States which have a direct bearing on food rationing in both its dietary and its administrative aspects. Great Britain depends heavily on importation of foodstuffs, the Ministry of Food owns approximately 98 per cent of the imported food supply, the nation geographically is small and cohesive, dietary habits are relatively uniform. The reverse of these factors obtains in the United States, which is primarily a food producing nation, where shortages for which no substitutes are available are unusual. The problem has been one of assuring equitable distribution and of insuring against the obtaining of more than a fair share by the less scrupulous.

GENERAL CONSIDERATIONS

The recommendations of the Subcommittee on Medical Food Requirements have been formulated in the light of present needs and restrictions. Recognition is made of the fact that poultry, fish and eggs, fresh fruits and vegetables are not at present rationed, that meats and fats are rationed together on "red points", that rationing of whole milk, in regions where it has been instituted, is imposed at the level of the producer and distributor rather than of the consumer, and that overall food supplies, though curtailed, are adequate to provide generous rather than minimal allowances. Nor should these recommendations be interpreted as representing optimal allowances for it is recognized that in some instances they might be materially further reduced, if necessary, without jeopardizing the health of the individual. It should be clearly recognized that these recommendations represent no attempt to provide an exclusive compendium of conditions in which extra rations are thought medically indicated. They are rather a guide to the vast majority of such conditions, any attempt to define all of which would vitiate the scientifically necessary flexibility inherent in any wise system of rationing for the sick. They are susceptible of revision as changing conditions dictate.

And, finally, with these last considerations in mind, the subcommittee is fully aware of the desirability of organizing medical appeal committees composed of appropriately qualified physicians, whose duty it should be to evaluate and pass on requests for additional food allowances for patients with conditions not already specifically stipulated as qualifying them for extra rations. In some areas such appeal committees have already been established by the field offices of the Office of Price Administration. The scientific necessity for appeal boards has already eloquently been testified to by the reported experience of one such panel.¹

DURATION AND CONDITIONS OF CERTIFICATION

It is the recommendation of the subcommittee that "authority" for certification of patients be restricted to persons licensed to practice medicine and surgery in their respective state.

Varying periods of validity for certification for extra rations are recommended. Where none is specified the following

¹ The Doctor Prescribes a Diet editorial New England J M 229 281 (Aug 26) 1943

recommendation of the Subcommittee is pertinent "Certification of patients for special food requirements should be renewed once a year and, in case of change of residence, the patients' credentials of certification should be transferrable to the local board having subsequent jurisdiction"

ADVICE ON USE OF RATION POINTS

Recognizing that many patients would benefit by and would welcome advice on how most intelligently and economically to use their ration points, the subcommittee recommended that an invitation be extended to the American Dietetic Association to assist the local ration boards in a voluntary advisory capacity. In response to this request the Diet Therapy Section of the American Dietetic Association, through its chairman, Miss Dorothea Turner, has expressed willingness to cooperate in such a capacity.

RECOMMENDATIONS

The following recommendations are for maximum allowances. Consideration, in prescribing them, should be given to the availability of unrationed foods which may in part or in full, be substituted for dietetically equivalent rationed foods. Examples of such possible substitutions under present rationing restrictions, are fish, poultry, eggs for rationed meats and cheese, cream and, to a lesser extent peanut butter and mayonnaise for butter and margarine, fresh for processed fruits and vegetables. The prescribing physician should bear in mind that there are other excellent sources of dietary protein, notably the legumes.

DIABETES MELLITUS

"Provisions for patients with diabetes mellitus may need to include per week not more than meat, including fish and poultry, 64 ounces bacon 8 ounces, butter or margarine, 16 ounces other fats and oils 7 ounces, eggs, 7, milk, adults, 7 pints, milk children to age 16, 7 quarts, fruits and vegetables, 72 ounces. This allowance applies only to processed fruits and vegetables. It does not indicate total carbohydrate requirements. If these amounts of food are not available to the patient from the rationed foods to which he normally would be entitled together with commodities obtainable from unrationed sources, sufficient supplementary ration points should be allotted to provide them.

'To be eligible to receive any supplementary allowances of rationed foods, the patient with diabetes mellitus must surrender his sugar ration.'

TUBERCULOSIS

A generous allowance of processed citrus fruits and tomato juice for patients with active tuberculosis has the endorsement of the Subcommittee on Tuberculosis of the National Research Council. It is directed toward providing an ample intake of ascorbic acid and should be regarded as a maximal allowance and not a recommended optimal allowance. When fresh citrus and tomato juice are available, they are to be preferred, in view of the unsatisfactory and uncertain content of much of the processed juice. The recommendation is as follows:

Patients with active tuberculosis should receive not more than 56 ounces of processed citrus fruit and tomato juices per week in addition to their ordinary allowance of processed fruits and vegetables and the following allowance of meats including fish and poultry, eggs, milk and fat and oils per week: meats, including fish and poultry, 64 ounces eggs, 7 milk, 7 quarts, fats and oils, including butter and margarine, 13½ ounces. If these amounts are not available from rationed foods together with unrationed food procurable by the patient, sufficient supplementary points should be allotted to provide them."

CHRONIC NEPHRITIS, NEPHROTIC TYPE, CIRRHOSIS OF THE LIVER, SEVERE HEPATITIS, AND CHRONIC ULCERATIVE COLITIS

The rationale for a high protein diet in nephrotic nephritis, cirrhosis and hepatitis may be disputed; many physicians will prefer to prescribe otherwise but there is an increasing body of scientific evidence to substantiate the following recommendation:

Patients with the nephrotic type of chronic nephritis, cirrhosis of the liver, severe hepatitis and chronic ulcerative colitis should be allowed a maximum of 7 pounds of meat (including fish and poultry) per week.

"A diagnosis of chronic ulcerative colitis should not be recognized unless certified to by three physicians and that certification must be renewed every four months and may be authorized by one physician."

CHRONIC SUPPURATIVE DISEASES

The importance of maintaining a positive nitrogen balance to favor wound healing and tissue repair has been conclusively demonstrated, likewise, that there is a large and significant loss of nitrogen in the pus from profusely draining lesions. Adequate replacement of this loss may be of critical value. In view of this subcommittee recommended that:

"Provisions for patients with chronic suppurative processes, especially empyema, osteomyelitis, extensive suppurative lesions of soft parts, subcutaneous tissues or muscle and those infections in which there is profuse pus formation, may need to include, per week, meat, including fish and poultry, 64 ounces, milk 7 quarts, eggs, 7.

"Certification of patients with chronic suppurative diseases must be renewed at sixty day intervals."

SRUPE

The sprue syndrome, including tropical and nontropical sprue and celiac disease, is characterized by faulty absorption from the gastrointestinal tract, especially of fat. Carbohydrate is better absorbed and protein is relatively well digested and absorbed. Present evidence suggests that the sprue syndrome represents a deficiency disease and that the unknown replacement factor is present in liver. The milk recommended should be skimmed. The recommendation follows:

Patients with sprue may need up to 7 pounds of lean meat including nonfatty fish and poultry and from 14 to 21 quarts of milk per week. Sufficient supplementary ration points should be allocated to provide what is required but in no case more than the maximum amount allowable.

"A diagnosis of sprue should not be recognized unless certified to by three physicians."

EVAPORATED MILK

There are many areas in the United States where fluid milk, for reasons of production, transportation or storage, is relatively unobtainable. This is especially true of certain areas in the South and Southwest. These recommendations are made with such areas especially in view. The needs of infants and children are envisioned in the first of the following group of three recommendations:

"In areas where unrationed fluid milk is not available, 1 pint of evaporated milk should be considered the equivalent of 1 quart of whole milk and should be made available in the amounts recommended to patients for whom milk is specifically indicated."

Evaporated Milk for Pregnant and Lactating Women—"In areas where unrationed fluid milk is unobtainable, pregnant and lactating women should be allowed sufficient extra points to provide 1 pint of evaporated milk daily."

Evaporated Milk and Frozen Foods for Hospitals—When hospitals are demonstrably unable to procure satisfactory substitutes in whole or in part for evaporated milk and for frozen foods in large containers, allocation to them of points in amounts adequate to provide the equivalent dietetic needs of their patients should be made.

Amendment 116 of Ration Board No. 5 allows ration boards to grant necessary supplementary allowances to hospitals on request of the administrative officer.

COFFEE

At the time of writing this recommendation is academic. However the attention of the subcommittee had been called to numerous claims for extra rations of coffee on grounds of therapeutic need. All such claims were considered unjustifiable and the subcommittee recommended that coffee is not an essential dietary substance.

ADMINISTRATION

The administrative aspects of rationing as they apply to the sick and institutions caring for the sick have been of necessity considered in the formulation of recommendations. For instance,

to define a hospital for purposes of rationing involves considerations apart from those which would dominate a definition for other kind of public health purposes. Such a definition has been formulated.

A form simple, clear and practical, designed best to fulfil the needs of the prescribing physician, his patient and the local rationing board to which the request must be referred, is necessarily likewise an important part of the mechanisms of food distribution. A form fulfilling these requisites is suggested.

And finally provision for appeal such as will assure equitable consideration of the needs of the patient, the judgment of his physician and the best interests of the public welfare is inevitably a keystone in any scientifically contrived structure of rationing and food distribution for the sick.

The following are the recommendations of the Subcommittee on Medical Food Requirements for such a structure.

Definition of a Hospital—A hospital, for purposes of rationing may be defined as an institution which maintains and operates in conformity with local and state laws, organized facilities for the diagnosis or care or treatment of human illness including convalescence and care during and after pregnancy where persons may be admitted, under the care of a person licensed to practice medicine and surgery in the state in which the institution is located, excepting such institutions as provide exclusively for medical care over periods of less than forty-eight hours.

Form for Certification of Patients—This is presented in the accompanying tabulation.

Form to Be Executed by Patient

To Ration Board No. _____ state of _____
I hereby request an extra allotment of such rationed foods as have been designated for the disease with which I am suffering, namely

(name of disease), and hereby
authorize my attending physician,

(name of physician)
to certify to the existence of such disease for the purpose of obtaining the designated foods.

(Signature)

(Address)

(Date)

(Number of ration book)

Form to Be Executed by Physician

I hereby certify that I have examined
that my diagnosis of his (her) condition is _____
and that he (she) has been under my care for _____ months.
I further certify that he (she) needs the amount of food specified
for the disease for 2 4 6 8 10 12 months
(encircle appropriate number)

(Signature)

(Degree)

(Address)

(School of graduation)

(State and year of licensure)

(Date)

Medical Advisory Boards—"Local ration boards should be instructed to refer all requests for special dietary consideration to a Regional Medical Appeal Committee, except where such special consideration is provided for under the list of diseases specifically accorded supplementary dietary allotments."

"In regions where advisory committees have not been formed, the subcommittee recommended that the central office in Washington advise the regional board to appoint such a committee, emphasizing the importance of selecting highly qualified leading representatives of the various fields of medicine concerned with problems of nutrition, such as internal medicine, surgery, obstetrics, dermatology, pediatrics and hospital administration."

"Where such committees are already in existence, the advisability of supplementing or reorganizing them to insure qualified representation in these specialty fields was emphasized."

CONCLUSIONS

Food rationing, as it affects the sick and institutions caring for the sick, presents certain problems, scientific, social and administrative. 1 It is of primary concern that the dietary needs of the sick be assured. 2 Since extra allowances of rationed foods granted to the sick must be drawn from the total supply available for distribution to the public, strict criteria of need should determine eligibility for such extra rations, and these rations should conform in amount to scientifically established allowances. 3 Provision should be made for administration such that the best interests of patient and public are equitably served.

The Subcommittee on Medical Food Requirements of the National Research Council submits recommended allowances for patients suffering from certain diseases and suggests certain procedures for assuring the dietary needs of the sick.

NAVY

MEDICAL AND DENTAL STUDENTS APPLYING FOR NAVY ENLIST- MENT OR TRANSFER

The Bureau of Naval Personnel of the Navy Department, Washington, D. C., in Naval Officer Procurement Circular Letter No. 11-43 Navy V-12 Bulletin No. 98, Subject G, in a release dated September 27 in regard to medical, dental, premedical and predental students applying for enlistment in or transfer to V-12 program for appointment as ensigns H-V(P), gives the following information:

Apprentice seamen class V-12, U. S. Naval Reserve, who enter the Navy V-12 Program direct from civil life will be assigned to premedical or predental training on the basis of their standing in the V-12 test taken prior to enlistment. Selections will be made from among candidates who indicate at time of enlistment their preference for medical or dental training, apprentice seamen class V-12 who express such a preference and are not selected for assignment to premedical or predental training will be assigned to another curriculum in the Navy V-12 Program.

Qualified civilians between the ages of 19 and 30 who are in attendance at or accepted for the next convening class of an approved medical or accredited dental school, and who wish to complete their medical or dental education on inactive duty at their own expense should make application for appointment as

ensign H-V(P) as heretofore. Successful applicants will be appointed ensigns H-V(P) and will remain on inactive duty until satisfactory completion of the prescribed course.

Qualified civilians who are in attendance at or accepted for the next convening class of an approved medical or accredited dental school and who wish to be ordered to active duty in the Navy V-12 program should, if 17 years of age, apply for enlistment as apprentice seaman class V-12(S) or, if between the ages of 18 and 30, apply for induction as apprentice seaman class SV-12(S). If there is an appreciable lapse of time between completion of premedical or predental work and beginning of medical or dental school, students selected for medical and dental training will be placed on active duty under instruction in naval hospitals or in other naval activities as apprentice seamen during the interim. Applications for enlistment as apprentice seamen class V-12(S), and for induction and subsequent enlistment as apprentice seamen class SV-12(S), should be processed in the same manner as applications for appointment as ensign H-V(P), including form B. N. P. No. 944 with the exception that officer applicant special qualifications report to the Congress may be omitted for SV-12(S) and V-12(S) applicants. The forwarding endorsement should indicate the specific classification desired, i. e. ensign H-V(P), apprentice seamen class V-12(S) or apprentice seaman class SV-12(S). The physical requirements for appointment as ensign H-V(P) U. S. Naval Reserve are as specified in chapter II of

Manner of the Medical Department. The physical requirements for enlistment as apprentice seaman class V-12(S) or for induction into class SV-12(S) are the same as for appointment as ensign H-V(P) with the following exceptions:

- Height Minimum 5 feet 4 inches
Maximum 6 feet 4 inches
- Vision 12/20 each eye correctible to 20/20
Color perception must be able to read correctly one plate of each of the following A O C color chart groups 1-4, 7-14, 17-22
- Weight In proportion to height
- Teeth Eighteen sound vital teeth, with at least two molars in functional occlusion and not more than four incisors missing which are satisfactorily replaced

Successful applicants for enlistment in class V-12(S) will be enlisted by the director or officer in charge on authorization by the Bureau of Naval Personnel. Successful applicants for induction in class SV-12(S) will be inducted in the following manner:

A candidate reported by the Bureau of Naval Personnel as qualified in all respects for class SV-12(S) will be given a form letter of directed assignment by the director [enclosure (A)], this letter will be addressed to the Commanding Officer, Armed Forces Recruiting and Induction Station, stating that he is in all respects qualified and acceptable for training in the officer candidate class, class SV-12(S) U S Naval Reserve. Each letter will have an expiration date not later than sixty days from date of issue. On receipt of the letter of acceptability the candidate will present himself to his local selective service board and volunteer for induction. If the candidate is not in a deferred classification, the local selective service board will send him to an armed forces recruiting and induction station for induction.

At the armed forces recruiting and induction station the candidate will present his letter of acceptability as an officer candidate to the commanding officer. The candidate will then be assigned to the Navy and forwarded to the nearest navy recruiting station for induction as apprentice seaman USN-I. After induction the candidate will volunteer for and be enlisted by the recruiting officer in, class SV-12(S), USNR and returned to inactive duty. Recruiting officers have no responsibility for investigation of citizenship, character or general acceptability, as suitable investigation of such candidates will have already been made.

The same forms will be used for inducting SV-12(S) candidates as are prescribed by Recruiting Circular Letter No 6-43 for Apprentice Seamen USN-I, and will be distributed in the same manner. Recruiting stations will forward all enlistment papers to the Office of Naval Officer Procurement which originally processed the applicant. The Office of Naval Officer Procurement will forward to the Bureau of Naval Personnel all enlistment papers except the health and service records. The inductee will continue his education on inactive duty under the jurisdiction of the director of naval officer procurement until placed on active duty under authority from the Bureau of Naval Personnel.

Applicants for apprentice seamen class V-12(S) and class SV-12(S) will be retained on or returned to inactive duty and ordered to active duty as appropriate to the next convening term at medical or dental school, to the next convening term in a V-12 unit as a premedical or predental student, or to a U S naval hospital or other naval activity on completion of required premedical or predental work pending entrance to medical or dental school. Applicants who have completed their required premedical or predental work and whose induction is not completed in time to be ordered to medical or dental school should proceed to medical or dental school on inactive duty. They will receive active duty orders to report on the date of commencement of the next term in medical or dental school.

Civilian premedical and predental student applicants for induction and subsequent enlistment in class SV-12(S) who are married may be enlisted if in all respects qualified but such students will not be ordered to active duty until the commencement of the term in the medical or dental school for which they have been accepted. When an apprentice seaman class

V-12(S) or class SV-12(S) who entered the program unmarried is actually in attendance in a medical, dental or theological school under the Navy V-12 Program, he may marry. All other apprentice seamen in the Navy V-12 Program will not be permitted to marry until commissioned or otherwise eliminated from the program.

Ensigns H-V(P) who must complete one or more additional terms in order to meet the requirements for a medical or dental degree will be permitted to resign their commissions for the purpose of enlisting as apprentice seamen class V-12(S). These men may be enlisted as apprentice seamen class V-12(S) on presentation of their resignations to the director, if qualified physically or if they are able to present a waiver granted at the time of original appointment for any defects revealed in the examination which are of the same degree. The bureau will consider waiving defects of greater degree or other nonorganic defects. Resignation forms (in duplicate) of men found qualified physically by the directors should be forwarded to the Bureau of Naval Personnel via the Bureau of Medicine and Surgery. Resignation forms of men whose reports of physical examination are forwarded for recommendation should be held until the recommendation of the Bureau of Naval Personnel is received. Resignation forms (in duplicate) of men who are considered qualified for enlistment by the Bureau of Naval Personnel should then be forwarded as prescribed.

The director of naval officer procurement will arrange for physical reexaminations of ensigns H-V(P) who have undergone corrective surgery or dentistry or other treatment for physical defects in order to qualify as apprentice seamen class V-12(S). If the examination indicates the corrective measures to have been successful the director of naval officer procurement is authorized to proceed with enlistment and to forward the report of physical examination to the Bureau of Naval Personnel via the Bureau of Medicine and Surgery. The director of naval officer procurement is not expected to initiate the reopening of cases of ensigns H-V(P) who are rejected for enlistment in class V-12(S) because of correctible physical defects.

The papers required for enlistment in class V-12(S) of former ensigns H-V(P) are as follows:

- 1 Shipping Articles B N P 603, with part 2 carbon attached
- 2 Copy of pages 7, 8, 9 and 10 of Service Record B N P 952
- 3 Pension affidavit NRB form 70 (Duplicate to be retained with S R)
- 4 Service Record B N P 952
- 5 Application for Enlistment NRB Form 24A

All enlistment papers will be forwarded to the Bureau of Naval Personnel except service record, which will be retained by the appropriate director of naval officer procurement until the man concerned is ordered to active duty. On enlistment of these men the director of naval officer procurement concerned will request their health records as ensigns H-V(P) from the commandants of the naval districts who have custody of them. If the commandant is unable to supply a health record on request, the director of naval officer procurement may prepare one.

Apprentice seamen class V-12(S) who have resigned as ensigns H-V(P) should continue their normal educational program in civilian status until their resignations have been accepted and orders to active duty have been received.

Ensigns H-V(P) (medical) and apprentice seamen classes V-12(S) and SV-12(S) (medical) will, on completion of the requirements for the medical degree, be commissioned as lieutenant (jg) MC-V(G), U S Naval Reserve, if fully qualified therefor. They will then intern in civilian hospitals with which they have contracted (the Navy Department will not arrange for such internship) in an inactive duty status unless they have applied in accordance with V-12 Bulletin No 75 (subject C) and have been accepted for an internship in a Naval hospital in which case they will serve on active duty in the rank of lieutenant (jg) MC USN with the grade of acting assistant surgeon.

Ensigns H-V(P) (dental) and apprentice seamen class V-12(S) and SV-12(S) (dental) will, on completion of the requirements for the dental degree, be commissioned as lieutenants.

tenant (jg) DC-V(G), U S Naval Reserve, if fully qualified therefor. Those lieutenants (jg), DC-V(G), U S Naval Reserve, who have contracted for a civilian internship which has been approved by the Bureau of Medicine and Surgery will remain on inactive duty to serve such internship. Other students appointed lieutenant (jg), DC-V(G), U S Naval

Reserve, will be ordered to active duty and will be afforded an opportunity to submit an application for authorization to take the next regular examination for appointment as assistant dental surgeon with the rank of lieutenant (jg), DC-V(G), U S Navy. Examinations for the Dental Corps, U S Navy, are held not more than twice a year.

MISCELLANEOUS

NEW INFORMATION PROGRAM OF NATIONAL RESEARCH COUNCIL

Dr. Ross G. Harrison, chairman of the National Research Council, has announced the acceptance by the National Academy of Sciences, National Research Council, of a grant from the Johnson and Johnson Research Foundation in the amount of \$75,000. The grant was made to enable the Division of Medical Sciences of the council, under the chairmanship of Dr. Lewis H. Weed, to gather current medical information pertaining to the war effort and to disseminate summaries. The program of the Division of Medical Sciences of the National Research Council contemplates coverage of the various medical reports and bulletins which emanate from civilian and military activities throughout the world related to the present emergency. The enterprise should fill a much needed gap in the war effort in medicine. One of the greatest difficulties encountered in medicine today is the provision of adequate up to date information to the medical officers of the armed services both in this country and abroad, also to make the experience of war medicine available as far as possible to civilian physicians. It is contemplated that a central office will be organized in Washington so that the many reports coming from various agencies may be gathered in one place. These reports will be carefully indexed and abstracted, and when possible the information will be issued in published form and distributed to medical personnel.

Many of the observations and laboratory studies cannot be released today because of the classified information contained in them—information of military importance. Such materials will be carefully held until release may be made. Every effort will be made, however, to issue bulletins containing current advances in medical practice and medical research that are not military secrets but which should be made available to the medical profession at the earliest possible date. This material will form basic source material for later summaries of medical experience in the present world war. Data not only from the armed forces will be included but also from other federal agencies and from civilian enterprises.

The Johnson and Johnson Research Foundation appropriation to the National Research Council becomes immediately available, in accordance with present plans it will be utilized in the period up to June 30, 1945. A central office will be established and reporters will be appointed in various foreign countries, so that there will be a staff of special observers working under the direction of the central office in Washington.

In a global war the various theaters of operation present different medical problems in which climate, season of year, distribution of insects and distribution of disease all play different roles. Reports from different parts of the world will be of greatest medical importance, and it is hoped that out of the combined efforts much of significance will be achieved.

The informational service will be under the direction of the Committee on Information of the Division of Medical Sciences, which includes Dr. Morris Fishbein, chairman, Dr. John F. Fulton, Dr. Richard M. Hewitt and Dr. Robert N. Nye.

The Johnson and Johnson Research Foundation was established on Jan. 1, 1940 as a nonprofit philanthropic organization by Johnson & Johnson, New Brunswick, N. J., with the express purpose to devote full energy to research and development of products to serve the medical profession. It has supported both fundamental and developmental investigations and is currently sponsoring about one hundred projects. At the present time twenty-eight universities are carrying on research under grants from the foundation. The fields of medical interest which have largely been supported are pharmacology (including antiseptics), allergy and physiologic studies in pediatrics and human fertility.

CARE OF WIVES AND BABIES OF SERVICEMEN

The following announcement was made by the Office of War Information on September 29:

More than 200,000 additional wives and babies of servicemen will be able to receive maternity and infant care during the remainder of this fiscal year as a result of the additional funds which the Congress voted yesterday (Tuesday) to the Children's Bureau in a deficiency bill, Secretary of Labor Frances Perkins stated today (Wednesday).

"Servicemen and their families have reason to feel gratified and reassured that Congress has acted so promptly to replenish the funds needed to continue the maternity and infant care program, initiated last March," Miss Perkins said.

"With the additional \$18,600,000 now made available in deficiency appropriation by action of the House and the Senate within two weeks of their reconvening, there will be no interruption in this humanitarian service, which was threatened with termination through lack of funds.

"Since the first appropriation for this service made by Congress in March of this year forty-four states, the District of Columbia, Alaska and Hawaii have submitted plans for cooperation in this program to the Children's Bureau and have received approval from the bureau. Of the remaining four states, Colorado and Texas are at present working out plans, Louisiana and North Dakota have so far failed to submit plans.

"Cases of nearly 50,000 servicemen's wives and babies have been authorized for care between the time the first state, North Carolina, received approval of its plan on April 8 and September 1. At the rate at which state health departments are requesting funds, it appears that for the remaining months of this fiscal year care will be requested for 20,000 to 25,000 cases each month.

"All of us, citizens in general as well as servicemen and their families, owe a debt to the state health departments which have given devoted service, without any financial assistance from federal funds, to get this program working. A heavy burden of responsibility rests on these departments, which not only prepare basic plans of operation but carry the full administrative weight of the operation of the program within their states. The thousands of doctors who are caring for the wives and babies also deserve our enthusiastic commendation. For many of them this service imposes an extra claim on time that is already crowded. The spirit of cooperativeness and loyalty which physicians have shown has contributed in large measure to the reassurance our servicemen have a right to feel that we at home are providing adequately for the safe birth of their children."

An amendment passed with the deficiency appropriation Miss Perkins pointed out, limits the program to wives and infants of enlisted men in the four lowest pay grades. Between July 1 and October 1 wives and infants of servicemen in the top three grades below commissioned officers were also covered. These are now barred.

To obtain care under this emergency maternity and infant care program a serviceman's wife selects the doctor, either a private practitioner or a clinic physician whom she wishes to provide care, and obtains from him a simple application form. Her doctor completes the application and forwards it to the state health department or other public health agency which may designate. Both the doctor or clinic and the patient are then notified of the approval of the application. Similar notification can be made when medical care is needed by the child during the first year of life. Applications can also be obtained from the local Red Cross chapter, hospitals or local health

agencies. Payment for services is made by the state health department to the doctor or clinic and to the hospital, if one is used.

Complete maternity service is obtainable during the antepartum period, childbirth and six weeks thereafter, including care of complications, operations, postpartum examination and medical care for the newborn baby. Hospital care is paid for at ward rates whether patients are cared for in wards or other accommodations. The money cannot be used to pay part of the cost of luxury accommodations.

On the basis of latest reports from the states, the Children's Bureau indicates the total number of cases authorized in each state from the date of approval of state plans up to September 1 as follows:

Over 4000 Illinois, May 8 (date when plan was approved)
From 2,000 to 3,000 North Carolina, April 8, Michigan, May 12, Wisconsin, May 14, Indiana, May 12, Oklahoma, April 27, Kansas, May 21, Kentucky, May 8, New Jersey, April 27.

From 1,000 to 2,000 Mississippi, April 19, Missouri, May 29, Minnesota, June 4, South Carolina, April 17, Arkansas, May 4, Maryland, April 9, Utah, May 8, West Virginia, April 24, Florida, June 3, Connecticut, May 14, Nebraska, June 3.

Under 1,000 California, June 30, Washington, May 28, New Mexico, April 20, Ohio, August 2, Maine, May 4, New York, June 30, Montana, June 3, Arizona, May 8, South Dakota, May 21, District of Columbia, June 22, Delaware, April 29, New Hampshire, June 8, Idaho, May 24, Nevada, April 27, Wyoming, April 30, Hawaii, May 31, Iowa, June 30, Virginia, July 22, Tennessee, July 21, Alaska, July 10.

No record of cases yet available from these cooperating states: Georgia, August 18, Massachusetts, August 30, Oregon, September 18, Pennsylvania, September 20.

WARTIME GRADUATE MEDICAL MEETINGS

A three day session under the auspices of Wartime Graduate Medical Meetings will be given on October 18-19-20 in the Red Cross Building at the Station Hospital, Davis-Monthan Field, Tucson, Ariz. Lectures and demonstrations will include traumatic surgery of the abdomen, maxillofacial surgery, thoracic surgery, anesthesia, blood plasma and blood banks, neurology, neurosurgery, malaria, rheumatic fever, coccidiosis, mycosis, clinical significance of the μ factor and psychiatry. Among the physicians taking part are Drs. Henry K. Ransom, Tracy Putnam, Ernest Sachs, Claude Mason and many officers of the medical corps. A practically identical program was held at the station hospital at Kirtland Field, Albuquerque, N. M., October 13-14-15.

PRIORITY RATING FOR EGGS AVAILABLE TO HOSPITALS

The U. S. Department of Agriculture, Washington, D. C., issued a memorandum September 27 concerning the priority rating for eggs available to hospitals. While egg shortages, if they occur, are likely to be local and of brief duration, it is expected that egg dealers in shortage areas generally will undertake to supply hospitals voluntarily without the need of priority certificates. Priority certificates, however, will be issued to hospitals if they have exhausted all other means of obtaining eggs. Since military hospitals are assured of supplies under a different plan, only civilian hospitals will be eligible for priority certificates which will be issued by regional offices of the Food Distribution Administration. Hospitals which need help in obtaining their requirement of shell eggs or which want additional information should write to the office of the Food Distribution Administration at the address nearest them:

5 South Wabash Avenue, Chicago
421 Market Street, San Francisco
4-5 Wilcox Building, Dallas, Texas
150 Broadway, New York
700 Old Colony Building, Des Moines, Iowa
1536 Welton Street, Denver
Western Union Building, Atlanta, Ga.

AIR EVACUATION OF WOUNDED

United States and Canadian officers met recently in Canada and in Washington, D. C., to discuss allied interest in air evacuation of ill and wounded men. Air Commodore J. W. Tice, director of medical service for the Royal Canadian Air Force, Lieut. Col. Richard L. Meiling, Office of the Air Surgeon, Army Air Forces Headquarters, and Lieut. Col. R. T. Stevenson, commandant of the School of Air Evacuation at Bowman Field, Kentucky, participated. Commodore Tice and Brigadier B. Chussholm, director general of the Medical Service of the Royal Canadian Army, recently returned the visit by calling on Brig. Gen. David N. W. Grant in the Air Surgeon's office in Washington. The Royal Canadian Air Force is developing an air evacuation school similar to the one at Bowman Field, Kentucky. The officers are coordinating air evacuation wherever United States, Canadian and British troops are fighting.

PUBLIC HEALTH UNDER HITLER

Paris-Midi (North Zone) of June 22 asks whether the precipitous rise in prices of objects of primary necessity is justified. An ordinary household broom now costs 300 francs instead of 50 francs. In a big store a cup and saucer of ugly earthenware cost 70 francs, a simple bowl 35 to 40 francs and a glass tumbler 25 francs. The former prices were respectively 6, 10 and 2 francs. The cheapest toothbrush costs 82 francs instead of 8, and the shop girl whispers that it is the last to be had. This is alarming. It is always the last packet of cigarettes, the last kilogram of sugar, the last pair of trousers or the last beefsteak before the new rise in prices. A packet of cigarettes will then cost 140 francs and a toothbrush 110 francs. A luxury toothbrush costs 350 francs in a small shop near the Saint-Lazare station. A brush for cleaning the kitchen tiles costs 80 francs. The last piece of chamotte leather costs 500 francs. A marketing bag of waxed canvas, formerly costing 38 francs, cannot now be found for 175 francs. Writing paper is so dear that one love letter costs 7 or 8 francs. The street hawker's price is no better, as he sells stationary for 10 francs instead of the former 1 franc. A comb worth 3 francs now costs 30 francs. In a chain store a pullover of mixed wool and cotton costs 570 francs. At a furniture dealer's a small white stool costs 80 francs instead of the former 10 francs. A quite ordinary scarf at a shop on the boulevard Clémenceau is priced at 1,500 francs, or the monthly salary of a stenographer. A small haberdasher asked 7,000 francs for a dressing gown of artificial silk. In the windows of a big shop a kitchen suite consisting of five pieces of furniture of white wood was marked at 11,027 francs.

Social Demokraten of July 14 reports from a private source coming from Berne that in Marseilles pregnant women are barely allowed half the prescribed rations. Newborn babies in Paris weigh less than 3 Kg. According to Professor Ritchet more than 10 million French people are suffering from undernourishment. These and millions more, already in bad health, will be in great danger owing to their lack of resistance to epidemics of tuberculosis, typhus, skin diseases and scabies. It is expected that the famine in France will be as severe as in Greece.

According to DNB of June 30 it has become necessary to point out that oils for technical purposes of all kinds must not be used for the manufacture of food or for cooking. They are a serious danger to health. Even the consumption of small quantities of fat mixtures containing technical oils may have serious consequences. Therefore people must be warned urgently not to use technical oils to prepare food or even to grease baking tins.

Le Petit Parisien (North Zone, July 12) states that there are no strawberries or cherries available in Paris but wild strawberries and other luxurious fruit can be found at very high prices. The newspaper deplores that only people who can pay 150 to 200 francs for a kilogram of strawberries or 30 to 40 francs for one peach can eat fruit.

CONNECTICUT

Canada Sends Groups to Yale for Training in Health Education—Five brothers and two fathers, members of religious orders, will receive one year's training in health education and public health at Yale University School of Medicine, New Haven, under a cooperative program with six teaching orders with Dr. Jules A. Gilbert, Granby, Que., director of public health education, and with the financial assistance of the ministry of health, Quebec. On their return to Quebec the seven will devote themselves primarily to school health education work in the normal schools of their respective orders, in cooperation with the ministry of health.

Memorial Room to Dr. Trask—A memorial room in the Yale University School of Medicine, New Haven, dedicated to the memory of the late Dr. James D. Trask, has been completed and is now in use for lectures and seminars by the department of pediatrics. Dr. Trask, who graduated from the Sheffield Scientific School in 1913 and was associate professor of pediatrics at Yale, died on May 24, 1942 while serving as consultant to the Secretary of War in the investigation of epidemic diseases in the Army. According to the *New York Times* the decorating and furnishing of the memorial room were made possible by funds contributed by medical students, by alumni of the pediatric service of the New Haven Hospital and by other friends and associates of Dr. Trask.

DISTRICT OF COLUMBIA

Hospital News—A new 50 bed addition to the venerable disease hospital at Gillinget Municipal Hospital, Washington, was to be available by October 1 under the direction of Sidney Olansky, assistant surgeon, U. S. Public Health Service Reserve.

Dr. Abarbanel Awarded Prize—Dr. Abraham R. Abarbanel, fellow in obstetrics and gynecology, George Washington University School of Medicine, Washington, was recently presented with the foundation prize of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons for 1943. Dr. Abarbanel's thesis was entitled "The Spasmodic Action of Magnesium upon the Tetanically Contracted Human Uterus."

Memorial to Dr. Sofie Nordhoff-Jung—A convalescent ward is to be maintained in Georgetown University Hospital with \$290,000 bequeathed by the late Dr. Sofie A. Nordhoff-Jung, professor of gynecology emerita at the Georgetown University School of Medicine. The physician, who died on June 6, declared in her will that with the exception of small sums her whole estate would go to the hospital. A bequest of \$35,000 was left outright to the president and directors of Georgetown University, the sum to be added to \$15,000 previously given for the ward. The convalescent ward will be named as a memorial to Dr. Nordhoff-Jung and her husband, the late Dr. Franz A. R. Jung. In 1923 Dr. Nordhoff-Jung established a cancer prize to encourage researches in the etiology, prevention and treatment of cancer.

FLORIDA

Meeting of New Graduate Faculty of Medicine—On August 14 the first official meeting of the faculty of the department of medicine of the Graduate School of the University of Florida was held in Jacksonville with Dr. Turner Z. Cason, Jacksonville, director of the department, presiding. The tentative program for developing the department calls for the division of the department into eleven sections:

Section on Roentgenology, Dr. Joshua C. Dickinson, Tampa
Section on Internal Medicine, Dr. William C. Blake, Tampa
Section on Public Health, Dr. Henry Hanson, Jacksonville
Section on Pediatrics, Dr. Thomas E. Buckman, Jacksonville
Section on Ophthalmology, Dr. Shaler A. Richardson, Jacksonville
Section on Urology, Dr. Robert B. McIver, Jacksonville
Section on Obstetrics, Dr. Samuel R. Norris, Jacksonville
Section on Gynecology, Dr. Charles J. Collins, Orlando
Section on Otolaryngology, Dr. H. Marshall Taylor, Jacksonville
Section on Pathology, Dr. Lucien Y. Drenforth, Jacksonville
Section on Surgery, Dr. Edward Jelks, Jacksonville

In each section a staff of instructors who have been certified by their specialty boards will serve with the chairman. The work of the department will be carried on by the University of Florida with the cooperation of the state medical association and the state board of health with Dr. Cason in general charge.

as director. At the meeting Dr. Cason requested each section chairman to prepare a syllabus, appoint instructors and suggest the number of hours required and the time of year best suited to offer graduate work. The new department of medicine, which will conduct graduate courses and promote research in medicine and surgery, is the outgrowth of the annual graduate short course for doctors of medicine inaugurated about ten years ago (*THE JOURNAL*, April 17, p. 1296).

ILLINOIS

Dr. Goodloe Named Deputy Commissioner at Peoria—Dr. Ollie M. Goodloe, assistant director of county health work, Kentucky State Department of Health, has been appointed deputy commissioner and director of maternal and child health of the Peoria City Department of Health. He succeeds Dr. Hugo V. Hullerman, who was recently named chief of the division of maternal and child hygiene of the Illinois Department of Public Health (*THE JOURNAL*, July 10, p. 756). Dr. Goodloe, who graduated at the University of Louisville School of Medicine in 1932, was to take over his new work on October 1.

Advisory Committee to Assist Aid Commission in Help for Blind—An advisory committee consisting of four physicians and four other citizens of the state who are interested in the problems of the blind has been appointed to assist the Illinois Public Aid Commission in administering the state's program for the blind. Physicians on the advisory committee are Drs. Watson Gailey, Bloomington, Harry S. Gradle, Chicago, Charles H. Phifer, Chicago, and Walter D. Stevenson, Quincy. Citizen members of the committee are Herbert F. Geisler, attorney, Chicago, Miss Audrey Hayden, Chicago, executive secretary, Illinois Society for the Prevention of Blindness, Samuel S. Holmes, Highland Park, attorney, and Frank M. Lay, Kewanee, manufacturer. The committee will advise the commission on such special problems relating to blindness as examinations, remediable conditions, rehabilitation, employment and social adjustment and on relationships with existing services for the blind in the state. Assistance under the program will supplant the blind pensions now being furnished by the counties from funds provided jointly by the counties and the state. Blind assistance under the new program will be financed by the state and federal governments through the social security board. Grants under the new program are planned for award during October.

Chicago

Distinguished Service Award Goes to Nathan Davis—The Mississippi Valley Medical Society at its meeting in Quincy, September 30, presented its distinguished service award for 1943, consisting of a gold medal and certificate, to Dr. Nathan S. Davis. The citation accompanying the award acknowledged Dr. Davis's contributions as an investigator and clinician.

Dr. Koch Honored—Fred C. Koch, Ph.D., Frank P. Hixon distinguished service professor emeritus of biochemistry, University of Chicago, was guest of honor at a dinner in the Morrison Hotel, October 1, given by the Chicago Section of the American Institute of Chemists. Dr. Koch was presented with a scroll testifying to his numerous contributions in scientific research. Among the speakers were Hilton I. Jones, Ph.D., of the Chicago chapter of the institute, who was the toastmaster, Edward A. Doisy, Ph.D., professor of biochemistry, St. Louis University School of Medicine, St. Louis, Victor Conquest, director of research of Armour and Company and George K. K. Link, Ph.D., professor of plant pathology at the University of Chicago.

Physician's Conviction on Abortion Charge Upheld—The Illinois Supreme Court in Springfield upheld the conviction of Dr. Emil Gleitsman, Chicago, who was found guilty of murder by abortion in the Cook County Criminal Court in 1942 and was sentenced to fourteen years in prison. According to the *Chicago Tribune* the physician has a police record going back to 1928, when the grand jury refused to indict him for abortion. In 1934, the report stated, he was convicted three times on a charge of manslaughter by abortion but each time the supreme court reversed the conviction and the charge was eventually dropped. After the recent decision Dr. Gleitsman was surrendered by his bondsman and taken to the Cook County jail to await transfer to the penitentiary, it was stated.

LOUISIANA

Personal—Dr. L. Everard Napier, for twenty years professor of tropical medicine at the Calcutta School of Tropical Medicine, is visiting professor of tropical medicine at the University of Louisiana School of Medicine, New Orleans.

has also been appointed consultant on tropical medicine to the Secretary of War—On August 4 Ernest Carroll Faust Ph D, professor of parasitology and acting head of the department of tropical medicine Tulane University of Louisiana School of Medicine, New Orleans, was presented with a diploma of corresponding membership by the Academia Nacional de Medicina of Mexico

MARYLAND

Personal—Dr Herbert C Blake, Baltimore on August 16 was elected state commander of the American Legion—New appointments to the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, include those of Francis G Evans, Ph D, formerly instructor in zoology, Duke University, Durham, N C as assistant professor of anatomy and Robert S Anderson Ph D biophysicist Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York as assistant professor of physiology

MASSACHUSETTS

New Appointments to State Medical Board—Dr George L Schadt, Springfield was recently appointed a member of the state board of registration in medicine to fill the expired term of Dr Harry L Stevens New Bedford and Dr William F O'Reilly Lynn, to fill the unexpired term of the late Dr Francis R Mahony Dr H Quimby Gallupe Waltham is the secretary

MICHIGAN

Crippled Children's Society Changes Name—The Michigan Society for Crippled Children has changed its name to the Michigan Society for Crippled Children and Disabled Adults Percy C Angove, Detroit is the secretary

Physician Indicted for Conspiring Against Government—Dr Fred William Thomas Detroit was one of a group named by the Federal Grand Jury September 17 on charges of "conspiring under the wartime espionage act to supply the German government with information regarding defense and war moves of the United States" newspapers reported Conviction of the physician as charged could result in the death penalty or five to thirty years' imprisonment

Dr McKhann Joins Parke, Davis & Company—Dr Charles F McKhann has resigned as professor of pediatrics and communicable diseases at the University of Michigan Medical School, Ann Arbor to become assistant to the president of Parke, Davis and Company effective October 15 Dr McKhann, who will devote his time entirely to the scientific activities of the company, is also giving up his position as professor of maternal and child health in the School of Public Health at Michigan A graduate of the University of Cincinnati College of Medicine Cincinnati in 1923 Dr McKhann became associated with Harvard Medical School in 1929 where in 1940 when he joined the Michigan faculty, he was associate professor of pediatrics and communicable diseases He held a similar appointment in the Harvard School of Public Health From 1935 to 1936 he had been visiting professor of pediatrics at Peking Union Medical College Peking China He is vice president of the American Society for Clinical Investigation and in 1936 was president of the Society for Pediatric Research

MINNESOTA

The Judd Lecture—The eleventh E Starr Judd Lecture will be delivered in the Museum of Natural History Auditorium at the University of Minnesota Minneapolis December 6 by Major Gen Norman T Kirk surgeon general of the U S Army His subject will be "Surgery in War"

New Officers of Southern Minnesota Group—Dr Carle B McKaig, Pine Island was elected president of the Southern Minnesota Medical Association at the annual meeting held in Austin August 23 Dr Charles M Robilliard Faribault and Dr Charles L Sherman Luverne are vice presidents and Dr Austin C Davis, Rochester is secretary treasurer

Personal—Dr Gustaf A Hedberg assistant medical director of the Nopernung Sanatorium, has been appointed medical superintendent to succeed Dr Arthur T Laird who has held the position since its inception in 1912—Dr Heitor P Froes, Brazilian specialist in tropical diseases, gave a lecture on August 30 at the Mayo Clinic, Rochester, on 'Old and New Tropical Diseases in Brazil'—Dr William A O'Brien, director of postgraduate medical education at the University of Minnesota Medical School, Minneapolis has been awarded an honorary fellowship by the American College of Hospital Administrators for interest and service in hospital administration

MISSOURI

Physician Indicted on Narcotics Charge—Dr Donnell M Pearson Louisiana, was named in an indictment returned by the federal grand jury, September 17, according to the St Louis *Post-Dispatch* The physician is accused of acquiring narcotics for the purpose of supplying addicts and for failure to keep adequate records of his dispensation of the drugs The newspaper stated that the physician bought more morphine in the last two years than was used by all the St Louis hospitals

Fifty Years' Membership—On October 5 the following members of the St Louis Medical Society were honored at a meeting in recognition of their completion of fifty years in the practice of medicine Drs Orril L G Suggett Asheville N C Adelheid C Bedal, Kirkwood and Vilray P Blair, Arthur H Bradley Harry S Crossen, William Anton Hall, Joseph J Meredith, William Jackson Miller, Frederick P Parker, Ferdinand O Sturheim Joseph M Trigg, Harry R Barton all of St Louis, and Clarence M Nicholson Charlotte, C H, Vt The meeting also served to honor members of the society who are now with the armed forces The speakers included Philip A Shaffer, Ph D, dean of Washington University School of Medicine, who presented 'A Salute to Our Colleagues at the Front,' and Father Alphonse M Schwitalla S J, Ph D dean of the St Louis University School of Medicine, "Medicine and Our Victory"

NEW JERSEY

Dr Paton Celebrates Ninetieth Birthday—Dr Thomas L Paton, Paterson, reported in the newspapers as the oldest practicing physician in New Jersey, observed his ninetieth birthday August 15 Dr Paton has practiced fifty-five years in Paterson and for the past eighteen years has been medical inspector of the Paterson public schools The *Passaic Herald News* states that Dr Paton had worked as a textile engraver for eighteen years before he began the study of medicine at the College of Physicians and Surgeons, Baltimore, where he graduated in 1887

NEW YORK

Cancer Teaching Day—A cancer teaching day was held at the Black River Valley Club Watertown, October 14, under the auspices of the medical societies of the counties of Jefferson Lewis and St Lawrence, the state medical society and the state department of health The speakers were

Dr Ethel F Butler Ithaca Cancer of the Lung
Dr Walter T Murphy Buffalo What the Practitioner Should Know About Radiation
Dr Lloyd F Craver New York Significance of Enlarged Lymph Nodes
Dr Clyde L Randall Buffalo The Significance and Management of Abnormal Vaginal Bleeding

Medical Society Rejects Federal Maternity Care Plan—The Albany County Medical Society, in a resolution made public on October 1 approves the intent of the state health department for allocation of federal money for maternity care of servicemen's wives but attacks the methods provided as an infringement on the "individual rights and freedom" of the wives receiving benefits The resolution also states that the plan establishes "a direct government-physician relationship which we sincerely believe to be detrimental to the well-being of wives of service men and ultimately to the interests of the nation as a whole As a substitute for the plan the medical society proposed that allotments be paid to eligible wives and that they be permitted to use the funds as they see fit in paying hospital and doctors bills Officers of the society said it was stated in spite of its disapproval of the plan put into effect several weeks ago that no woman or child would lack medical care

New York City

First Harvey Lecture—Dr Harold G Wolff associate professor of medicine Cornell University Medical College will deliver the first Harvey Society Lecture of the current series at the New York Academy of Medicine, October 28 He will discuss 'Some Observations on Pain'

Russian Medicine—Dr Henry E Sigerist, director of the Johns Hopkins University Institute of the History of Medicine Baltimore, addressed the New York Society for Medical History, September 30, on 'Russian Medicine Past and Present' The address was discussed by Dr Jack M Rowe medical adviser to the Soviet Government Commission and Dr Arthur F Chace, president of the New York Academy of Medicine

The Niles Lecture—Dr Edward A Strecker professor and head of the department of psychiatry University of Pennsylvania School of Medicine Philadelphia and consultant to the Army Navy and Air Forces in psychiatry will deliver the annual Walter L Niles Memorial Lecture at Cornell University Medical College October 19, under the auspices of the Tau

Chapter of *Nai Simma Nu*. This subject will be "The Neuropsychiatry of Global War." The lecture is given annually in memory of Dr. Niles, a former dean of the medical college and for many years professor of clinical medicine at Cornell.

Drive for Funds Exceeds Goal—The first annual development fund appeal made by the Long Island College of Medicine, Brooklyn raised \$42,118, exceeding its intended total of \$40,000. The fund will be used to pay larger professional salaries, to provide departments with more technical assistance and to strengthen the teaching, research and service program in other ways. Gifts from business interests totaled \$13,158, contributions by the general public \$18,592, and the medical profession gave \$10,368. The effort represented the first step toward building up an annual educational fund of at least \$300,000.

Wartime Rules for Visitors in Hospitals—The posting in member hospitals of Blue Cross placards bearing wartime rules for visitors was announced recently by the Associated Hospital Service of New York. The visiting regulations request that visitors voluntarily restrict the frequency of their visits and send fewer gifts to patients, especially if the gifts require care. Visitors are further asked to make their stay as brief as possible, not to discuss war, illness or anything that will excite the patient and to speak quietly, walk softly and make no unnecessary telephone calls so that the telephone lines will be kept open for emergencies.

OHIO

One Hundredth Anniversary at Western Reserve—The week of October 24 will be devoted to a celebration of the one hundredth anniversary of Western Reserve University School of Medicine, Cleveland. Anniversary ceremonies will be held on October 27 and alumni clinics and commencement activities will take place on October 28. Among the speakers on October 27 will be Dr. George H. Whipple, dean of the school of medicine and dentistry, University of Rochester, N. Y., on "Blood Plasma Proteins: Their Production, Function, Substitution and Replacement" and Dr. Alan Gregg, director for the medical sciences, Rockefeller Foundation, New York, "The Matrix of Medicine." In the evening Dr. Reginald Fitz, Boston, will address a dinner on "The Crimson Thread." On October 28 the speakers will be

Dr. Horace M. Korns, Iowa City, The Modern Treatment of Chronic Congestive Heart Failure
Dr. Ralph M. Waters, Madison Wis., Indications for and Complications of Cerebral Anesthesia
Dr. Clarence D. Selby, Detroit, The Future of Industrial Medicine
Dr. Daniel B. Kirby, New York, One Hundred Years of Progress in Cataract Surgery
Dr. Marion A. Blankenhorn, Cincinnati, Multiple Peripheral Neuritis
Dr. Harry Goldblatt, Cleveland, Hypertension
Dr. Francis P. Corrigan, Caracas, Venezuela, S. A., Treatment of Malaria
Frederick C. White, Phila. D., Cleveland Episodes in One Hundred Years
Dr. Torald H. Sollmann, Cleveland, Farewell 1943, Hail 2043

OKLAHOMA

State Department Rejects Maternal Care Plan—The Oklahoma State Department of Public Health recently announced that it was withdrawing from participation in the federal maternal and child care plan. According to a report, a ruling by the attorney general of the state gave right of participation to any person, either a layman or a medical man. Under these circumstances the state health department was unwilling to continue its activities any further. Pending further notice, physicians who are caring for patients under the plan should now make other arrangements for remuneration, it was stated.

SOUTH DAKOTA

Lectures on Tropical Medicine—Dr. Marcos N. Fernandez, professor of pathology and bacteriology in the Marquette University School of Medicine, Milwaukee, toured South Dakota, September 19 to 26, lecturing on tropical diseases to medical groups in Aberdeen, Huron, Sioux Falls, Pierre, Rapid City and Fort Meade. The trip was sponsored by the South Dakota State Board of Health and the U. S. Public Health Service to bring the latest developments in tropical medicine to the medical profession of South Dakota.

Public Health Association Meeting—The annual meeting of the South Dakota Public Health Association was held in Huron, September 21, under the presidency of Dr. George L. Hickman, Bryan. A round table discussion was held on the "Problems of the Public Health Officer" conducted by Dr. Antony Triolo, Pierre, director of the divisions of maternal and child health and crippled children, of the state board of health. Other speakers included

Mr. I. R. Vaughn, Pierre, Vital Statistics and Public Health Education
Dr. Marcos Fernandez, Milwaukee, Tropical Diseases
Dr. William L. Meyer, Senator, Follow Up Technique in Tuberculosis
Dr. Gilbert Cottam, Pierre, Public Health in South Dakota

WEST VIRGINIA

Community Medical Service Plans Approved—Regional nonprofit medical service plans will be immediately developed as community projects with the endorsement and support of component medical societies in accordance with unanimous action of the council of the West Virginia State Medical Association on September 30. The project was submitted to the council in the form of a report of the fact finding and planning committee on September 29. As presented in the report, the plans will be operated by group hospital service with the joint supervision of an advisory committee elected by the county medical society and a central state committee appointed by the president of the state medical association. A medical service contract will be offered to the public on a periodic prepayment plan to pay the cost, in whole or in part, of surgical, obstetric and medical service while a bona fide patient in a hospital. The details of these plans and contracts will be left to each community and nothing will be done that might in the least interfere with the doctor-patient relationship, the patient to have the free choice of hospital and physician. Under the setup it will be the duty of the state committee, together with the committee representing hospital plans operating within the state, to formulate a basic contract, and particularly to see that this service is made available to every community of the state, with particular emphasis on rural areas. As the care of the indigent sick is a joint responsibility of the community and the medical profession, the report urges further study in each community toward improving such care if necessary. Each county society is urged, through a committee, to survey its plan for the care of the indigent sick and to report to the state fact finding and planning committee. The report also recommends that the public health work be extended and that measures be taken to assure adequate public health units for every county or group of counties, pointing out that the work of these units should be limited to preventive medicine, immunization, and particularly to education of the public in health matters.

GENERAL

Medical Woman's Journal Observes Fiftieth Anniversary—With the publication of its September issue, the *Medical Woman's Journal* completes fifty years. The publication was founded by the late Margaret Hackedorn Rockhill. Dr. Elizabeth Mason Hohl, Los Angeles, is the editor in chief.

Special Society Elections—Dr. Donald C. Smelzer, Philadelphia, was chosen president-elect of the American Hospital Association at its recent annual meeting and Frank J. Walter, Denver, was installed as president. Dr. Harley A. Hyman, Ann Arbor, is treasurer and George Bugbee, Chicago, executive secretary. Dr. Fred B. Moor, Los Angeles, was chosen president-elect of the Society of Physical Therapy Physicians at its meeting in Chicago, September 8, and Dr. William H. Schmidt, Philadelphia, was installed as president. Dr. William D. Paul, Iowa City, is vice president and Dr. Milton G. Schmitt, Chicago, is the secretary-treasurer. Dr. Miland F. Knapp, Minneapolis, was chosen president-elect of the American Congress of Physical Therapy at its twenty-second annual session in Chicago in September and Dr. Kristian G. Hamon, New York, was installed as president. Other officers include Drs. Richard Kovacs, New York, secretary, John S. Coulter, Chicago, treasurer and Walter J. Zeiter, Cleveland, executive director. The gold key of merit was awarded to Dr. Coulter.

New Home for Institute of Physics—A five story building at 57-59 East Fifty-Fifth Street, New York, formerly a private residence, has been acquired by the American Institute of Physics for its national headquarters and its affiliated scientific societies. The institute has been occupying rented space since its establishment in 1931. It is anticipated that occupying its own home will enable the group comprising the institute to carry forward their aims for "high professional standard improvement of publications and meetings improvement of the teaching of physics in high schools and colleges, expansion of facilities and resources for research, rehabilitation of interrupted careers and extended activities to advance the work of physicists." The American Institute of Physics is composed of the American Physical Society, Optical Society of America, Acoustical Society of America, American Association of Physics Teachers, Society of Rheology. Associated with the institute are the American Society for X-Ray and Electron Diffraction and the Electron Microscope Society of America.

Stamps for Cancer Fund Raising in Other Countries

—Fifty-one stamps have been issued by various countries that have been used to raise funds for the control of cancer and for the treatment of cancer, according to an article in the Bulletin of the American Society for the Control of Cancer. The stamps consisted of regular postal issues that prepaid postage on letters. Postal tax stamps were also issued. These did not pay postage, but their use was compulsory on every letter passing through the mails for certain periods of time. The money derived from the sale of these stamps provides for a cancer fund. The last type of stamps issued were semipostal stamps. These were sold for a premium over their face value to raise money for some purpose. The countries that have issued these stamps are Afghanistan, Cuba, Danzig, Denmark, Ecuador, France, French Colonies, Morocco, Norway, Panama and Sweden.

Child Care Units Only Partly Successful—A survey of manufacturing cities, reported in the *New York Times* September 24 shows that the child care centers and nursery schools, set up for the benefit of working mothers in areas where government contracts have increased the ordinary working conditions, are standing idle or are only partly utilized. Officials have agreed that the program, established by local initiative and by funds supplied by the Federal Works Agency, so far has proved only in part successful. Ignorance of the facilities provided to care for children while mothers work on the assembly lines was the explanation most generally offered. In New Jersey Dr. Ellen C. Potter, chairman of the child care committee of the New Jersey State Civilian Defense Office Trenton reported on September 30 that the child care centers for children of preschool and school age throughout the state are being ignored by working mothers who leave their children with neighbors or relatives when they go to work. To date she said, twelve communities in the state have received Lanham funds for community centers and five grants are pending. On September 15 registration at seven units was 230 but actual attendance was down to 187. Reasons for the poor showing given by some mothers were the difficulty in transporting children to and from the nurseries in getting both children and mothers ready in the morning and fathers objecting to having family life dislocated.

MEDICAL BILLS IN CONGRESS

Bills Introduced—The President has transmitted to the Congress supplemental estimates of appropriation for the Public Health Service as follows: (1) an estimate of \$10,000,000 to be used in carrying on the nurses' training program for the period Jan 1 to March 31, 1944 (H. Doc. No. 311) and (2) an estimate of \$2,350,000, an undisclosed part of which will be used for the supplying by the Public Health Service, on request of state authorities, of needed medical and dental care, either by temporary financial aid or by direct employment of doctors and dentists, in certain critical areas where acute shortages have developed (H. Doc. No. 321). Under the latter estimate too the Public Health Service would be authorized to assign its medical and dental personnel to critical areas when so requested by a state department of health. The services of such personnel it is proposed, will be furnished the public in accordance with schedules of fees approved by the state health departments and the Surgeon General of the United States, which fees will be collected by and used at the direction of the state departments of health, to defray the expenses thereof incident to the rendition of such medical and dental services. Any balances remaining at the end of a fiscal year will be covered into the treasury as miscellaneous receipts. These estimates are pending in the House Committee on Appropriations. H. R. 3379 introduced by Representative Bulwinkle, North Carolina proposes to codify the laws relating to the United States Public Health Service. According to Representative Bulwinkle, this bill is designed to bring together in one enactment all of the laws relating to the Public Health Service to permit the administrative reorganization of the service to adjust the wartime status of the commissioned corps of the service to reconcile the conflicts and eliminate the overlapping in the law and to make certain mechanical revisions found necessary by long administrative experience. This bill, in the words of Representative Bulwinkle, is in no sense a measure designed to place the Public Health Service into new fields of operation or to enlarge its functions and powers. Its sole purpose is to enable the Public Health Service to perform its present statutory functions more effectively.

LATIN AMERICA

Health Activities in Latin America—Dr. George C. Dunham, formerly director of the division of health and sanitation of the coordinator of Inter-American Affairs, on September 2 was appointed executive vice president of the Institute of Inter-American Affairs and assistant coordinator in charge of the basic economy department. Dr. Albert R. Dreisbach was named director of the division to succeed Dr. Dunham.

Construction—A 14 bed hospital was established in La Boca Camp during July along the eastern border of Lake Yojoa, Honduras. A 50 bed hospital and health center is planned in Paraguay by building an addition to the existing 18 bed Barrio Obrero Hospital.

Search for Cinchona—According to the *Inter-American Economic News* a hitherto undeveloped cinchona area has been surveyed in the Balsa Pampa region of Central Bolivia. A number of new cinchona regions have been discovered in Peru and in the Huari Huari Valley.

Leprosy Control Program—Dr. Manuel Gimenez Uriarte has been appointed director of the Colony at Sapucay by the minister of health of Paraguay. It has also been proposed that Dr. Uriarte, who has recently returned from Rio de Janeiro from a fourteen months study of leprosy, be in charge of the clinic and isolation hospital facilities for patients with leprosy planned for Asuncion.

Malaria—Malaria control activities are a major development in the health and sanitation of the Amazon Project in Brazil where the disease is the chief cause of morbidity and mortality. A number of medical posts have been established to provide dispensary medical care and serve as the centers for malaria control activities. In Marmelade, Haiti sixty deaths from malaria had occurred during the three months prior to July 22. The town of Marmelade has a population of less than 1,000 persons.

Fellowships—The John Simon Guggenheim Memorial Foundation, New York, recently awarded fifteen fellowships to Latin Americans seven to biologists.

Jose Antonio Goyco, assistant in chemistry, School of Tropical Medicine, University of Puerto Rico, Santurce, P. R.

Mario Autuori, assistant in the Biological Institute, Sao Paulo, Brazil.
Dr. Isabel P. Farfante, instructor in zoology, Faculty of Science, University of Havana, Cuba.

Juan Ignacio Valencia, agrostologist, Darwin Botanical Institute, Buenos Aires, Argentina.

Raul Cortes Pena, entomologist, Ministry of Agriculture, Santiago de Chile.

Dr. Gabriel Gasic Livacic, chief of the Laboratory Institute of Biology of the University of Chile, Santiago de Chile.

Dr. Fabio Leon Werneck, chief of the laboratory, Instituto Oswaldo Cruz, Rio de Janeiro, Brazil.

Tuberculosis—The News Letter of the Health and Sanitation Division states that tuberculosis ranks second only to malaria as a major public health problem throughout the other American republics. It is the principal cause of death in Lima, Sucre, Rio de Janeiro and Caracas. Tuberculosis control programs are being conducted in Colombia, Ecuador, El Salvador, Honduras, Nicaragua and Paraguay. Plans are being formulated to include Bolivia, Chile and Peru. Tuberculosis dispensaries have been established. In Nicaragua the national department of health has an administrative division for tuberculosis. The tuberculosis control project started there seeks to provide the health department with adequate space and equipment necessary for tuberculosis control throughout the country and to train public health nurses to carry on tuberculosis work. In Ecuador a 300 bed tuberculosis hospital is now being constructed at Guayaquil.

Floating Launches—For the Amazon project in Brazil a fleet of boats is planned some to serve as floating dispensaries to take medical supplies to the isolated scattered population groups along the rivers and others to serve as ferries to transport medical personnel and supplies. Twenty of these launches have already been placed in operation. The dispensary launch *Constantino* returned during July to Iquitos, Peru from a months trip on the Amazon and Marañon rivers and the lower part of the Pastaza and Morona rivers. During the trip the launch visited 101 settlements, villages or groups of houses. A total of 674 patients were treated and 512 for intestinal parasites. 101 for malaria and 73 for yaws. During this trip all of the military garrisons along the river were visited and medical care was given to any of their personnel who were ill. Narcotrine distribution points were established at San Lorenzo, Nauta, Tamchivacu and Concordia.

LONDON

(From Our Regular Correspondent)

Aug. 27, 1943

Nervous Disorders of Swallowing

At the Laryngological Section of the Royal Society of Medicine, Sir Arthur Hurst dealt with nervous disorders of swallowing, a subject on which he has done important work. His researches on the sensibility of the alimentary tract have shown that tactile sensibility extends beyond the mouth to the junction of the pharynx and esophagus but no farther. However, the esophagus is sensitive to cold and heat, though thermal stimuli produce no sensory response in the stomach, and distention produces a feeling of fullness which merges into pain when the stimulus is increased. Consequently if food is masticated until it is semifluid and has acquired the body temperature, its passage beyond the pharyngoesophageal sphincter is not appreciated, but if swallowed in unchewed lumps while still hot or cold its passage can be felt as far as the cardia. The esophagus being a fixed organ localization of sensory response to thermal and distention stimuli is accurate.

Theoretically there is no reason why hysterical dysphagia should not develop in the form of paralysis or incoordination of the voluntary muscles concerned in the first two stages of swallowing in which food passes through the sensitive buccopharyngeal cavity. But it would be unlikely to develop in the esophagus or at the cardia, as the passage here is entirely independent of voluntary action and normally is not felt, the food disappearing into the void after passing the pharyngoesophageal sphincter, except when very cold, very hot or in large lumps. Hysterical dysphagia is rare. In the last war Hurst saw more than 100 cases of hysterical aphonia and over 50 of hysterical vomiting in soldiers but no case of hysterical dysphagia.

Dysphagia may occur in various organic nervous diseases as a result of paralysis of the muscles concerned in the first and second stages of swallowing. The esophagus itself and the cardia are never involved. In diphtheria the toxin ascends by the lymphatics of the nerves from the site of the lesion to the central nervous system, where it puts out of action the corresponding nuclei. Therefore the paralysis of the soft palate which results in regurgitation of food through the nose, and the rare pharyngeal paralysis which results in severe dysphagia, occur only in faucial diphtheria. In motor neuron diseases, which include progressive muscular atrophy and amyotrophic lateral sclerosis, dysphagia may occur if the vagal nucleus is involved. It always occurs in progressive bulbar palsy. Myasthenia gravis, though a primary muscular disease, produces a similar upper dysphagia. Upper dysphagia in anemic women was first described by R. D. Paterson in 1906 but attracted so little attention that it was redescribed as the Plummer-Vinson syndrome. Hurst therefore calls it Paterson's syndrome. It occurs in about 15 per cent of cases of simple achlorhydric anemia, which is common in women, especially in those between 30 and 50. It is the direct result of iron deficiency, which causes not only the anemia but also atrophy of the mucous membrane of the tongue and pharynx, cracks at the angles of the mouth, loss of teeth and spoon shaped brittle nails. The atrophy of the pharyngeal mucosa results in loss of sensibility, so that the afferent side of the reflex, on which the second stage of swallowing depends, is impaired. Treatment consists in administration of iron, which often restores to normal the atrophied mucosa. In neglected cases this may undergo malignant degeneration.

The commonest nervous disorder of swallowing is achalasia of the cardiac sphincter. It produces stagnation of food and dilatation of the esophagus, although there is no organic obstruction. The complete absence of hypertrophy of the sphincter

found post mortem shows that cardiospasm is not the cause, as was believed. In 1915 Hurst suggested that the obstruction might be the result of absence of relaxation of the sphincter. He believes that this accounts for every case of megaesophagus. In 1924 he suggested that it might be due to organic disease of Auerbach's plexus, which proved correct. The simplest and most effective treatment is by means of mercury bougies, which Hurst devised in 1913.

Too Many Facts

In his introduction to the fifth edition of McGregor's Synopsis of Surgical Anatomy, the professor of anatomy at Witwatersrand University, R. A. Dart, discusses a problem which the vast increase of human knowledge has rendered pressing. It has been stated that the brain of man can absorb only 200,000 distinct facts. But the one subject of anatomy is so great that if a student absorbed the whole he would, according to this calculation, have no mental room left for the absorption of anything else. In 1756 the surgeon Cheselden published a textbook of anatomy in which he was able to dispose of the whole subject in three hundred and thirty-four pages of text and sixteen of index. Today the subject has reached such monumental proportions that in one book the index occupies 113 pages and contains sixteen thousand subject references. Professor Dart describes the unfortunate student as called on to memorize an excessive number of isolated facts not lending themselves to logical connection or correlation in our present state of knowledge. He therefore requires the help of supplementary books written by discerning men whose single ambition is to provide the examination candidate with much needed assistance in a difficult situation and the prospective surgeon with the more significant anatomic facts relevant for practical application. This is what McGregor has done in his eminently successful book.

Too many facts (or alleged facts, for which life is too short), have become a difficulty in every branch of medicine. One way of surmounting it is by specialization which, though it has already reached a high degree, still goes on. But the loss of breadth of view, and even of common sense, of the specialist mind has become proverbial. Further, not all can become specialists, there remains a sphere which can be filled only by the general man. The remedy seems to lie in the fact that the advance of science involves development as well as growth. Knowledge becomes more definite and new principles are formulated. The accumulated facts are seen to be only examples of these principles and can largely be dispensed with in teaching. But new principles develop all too slowly, while new facts, or more often alleged new facts, accumulate at an enormous rate. Hence the increased size and increased number of our journals and books, for which, again, life is too short.

The Clinical Picture of Gas Gangrene

Gas gangrene due to *Clostridium oedematis maligni* is often overlooked in its early stages. The *Army Medical Department Bulletin* therefore calls attention to the more detailed clinical picture recently given. An important early symptom is a swelling of weight in the affected limb (or amputation stump) followed in two to eight hours by much local pain. Considerable edema soon appears, accompanied by profuse yellowish or brownish yellow serous discharge from the wound. Blood stained discharge seldom, if ever, occurs. Gas has not been a noticeable feature. Diagnosis must not depend on the detection of smell, since it occurs only when there is gross contamination with other organisms. Discoloration of skin appears late.

The general condition is poor, for the toxemia is out of proportion to any obvious local lesion. The pulse is rapid and of poor volume and the blood pressure falls low at an early stage of the disease. Pyrexia is not remarkable, seldom over 101° F. If there is much oozing hemoglobin may rise to 139 per cent. Mental changes are not prominent. The affected limb is

grossly swollen shiny and in the early stages, firmer than normal. At first they are pale but later become dark purple, friable and almost deliquescent. Essentially the picture is one of severe toxemia with little local reaction other than swelling. It is important that this local lack of obvious signs in the wound should not delay diagnosis.

Artificial Insemination

In the House of Lords Lord Brabazon drew attention to recent advances in regard to insemination. He understood that in the United States there was an increasing demand that, if a husband was sterile, his wife rather than adopt a child, should be inseminated by an unknown father. It was estimated that there were ten thousand applicants among childless couples. A child so produced would be regarded by the world as legitimate, and only the doctor would know the truth. This was open to grave abuses. Some women might prefer to have children without marriage. The church would have to face that question.

Viscount Bledisloe hoped that in this country we would do everything to discourage a process which could only in the long run tend to break down family life. For the government the duke of Norfolk, joint parliamentary secretary to the Ministry of Agriculture, said that the minister of health was closely watching the question. Artificial insemination in animals today provided a means of improving live stock. The use of a valuable sire could be extended. A small farmer was able to use a sire which he could not otherwise. In certain respects the process was a safeguard against spreading disease. Two large experimental stations had been set up.

Improvement of the Milk Supply

The government has decided on a progressive policy for the improvement of the milk supply. The basis of a sound milk policy must be a well bred healthy dairy herd. At present many herds are not inspected at all. It is proposed to arrange for a minimum of one inspection each year of every dairy herd and to inspect more frequently those herds with a bad disease history or where the milk is not heat treated before sale. Owing to transport difficulties much of the tuberculin tested milk now produced is bulked with ordinary milk. To encourage the production of this valuable milk the government proposes to pay a uniform production premium of 8 cents a gallon. The minister of food will take steps to insure that as much milk as possible from tuberculin tested herds is sold to consumers under proper label. The price will be only slightly higher than that of ordinary milk. In certain areas where the policy is possible the government will prohibit the sale of milk to the public unless it is either (1) from tuberculin tested herds, (2) accredited milk sold by a retailer who sells the milk of a single accredited herd or (3) rendered safe by heat treatment.

Death of Sir Beckwith Whitehouse, President of the British Medical Association

Sir Beckwith Whitehouse, president of the British Medical Association, died suddenly after attending a meeting of the council. He was in his sixty-first year. After a distinguished university career he settled in Birmingham as an obstetrician and gynecologist. In 1924 he was appointed professor of midwifery and diseases of women at the university, a chair previously held by Lawson Tait. A brilliant expositor and skilful operator, he was a powerful influence in the medical school. He originated some surgical procedures and invented a cecal retractor for appendectomy, by which the appendix and part of the cecum were isolated from the peritoneal cavity and edges of the wound. In 1933 he visited the United States at the invitation of the American College of Surgeons of which he was made an honorary fellow. He was also made an honorary fellow of the Canadian Medical Association. He edited the fourth edition of Eden and Lockyer's *Gynecology* which was published in 1935. In the last great war he served as an officer in charge of a surgical division.

Aug. 31, 1943

A Survey of Hospitals

A chapter of the 1942 annual report of the director general of the Brazilian National Department of Health is devoted to the division of hospitals, created in the department a little more than a year ago. Dr. Theophilo de Almeida is head of the division. One of the first efforts of Dr. de Almeida was the organization of a roster of the hospitals of Brazil. Some averages computed from the first information gathered provide an interesting picture of the hospital situation of the country. At the end of 1942 a rather complete roster of the hospitals (only those with at least 25 beds are called hospitals) gave a total of 1,303 institutions for the whole of the twenty states, the Acre Territory and the Federal District (city of Rio de Janeiro). As Brazil has an area of 3,287,595 square miles and the 1942 population was reckoned at 43,027,000, each hospital has to serve an average of 2,523 square miles and 33,021 people. Owing to the large differences in the density of population and in the general development of the several sections of the country, these averages for the individual sections show notable variations. It seems strange at first glance that the Acre Territory should occupy the highest position, with 7.23 hospitals per hundred thousand of population, but this territory, far inland in the Amazon valley bordering Bolivia and Peru, has just a few centers of population where the federal government which directly administers this area, is doing good work to assist in the struggle against the great tropical scourges. With this exception the northern, tropical states have few hospitals—about 1 per hundred thousand of population. Above this level are only the states of Sergipe, Mato Grosso and Amazonas, respectively with 3.42, 3.39 and 3.04 hospitals per hundred thousand of population. The southern, more populated and more developed states are better equipped with hospital facilities. Minas Geraes 3.16 per hundred thousand, Rio de Janeiro 3.52, Parana 3.92, São Paulo 4.23, Santa Catarina 5.28 and Rio Grande do Sul 6.54. The Federal District, with 93 hospitals for 1,860,000 population, has exactly 500 hospitals per hundred thousand.

Out of this total of 1,303 hospitals 457 are specialized institutions (lying-in hospitals, hospitals for children, for tuberculous patients, for the leprosy, for nervous and mental patients and others). According to the report, the remaining 846 institutions, considered as general hospitals, have 58,820 beds, or an average individual capacity of 69.5 beds. The same source shows that this capacity also varies widely through the different states. The highest average rate of beds per hospital is that of the Federal District: the 42 general hospitals there have a total capacity of 8,433 beds, or 200.8 beds per hospital. Next come the states of Para with 124.3 beds per hospital, Piahy 99.3, Pernambuco 96.0, Mato Grosso 77.0, Amazonas 76.8, Rio Grande do Norte 74.6, São Paulo 73.3, Parahyba 72.9, Ceara 66.5, Rio Grande do Sul 62.6, Alagoas 62.4, Bahia 57.0, Minas Geraes 53.7, Rio de Janeiro 53.5, Maranhão 53.0 and Parana 50.4. The remaining states (Sergipe, Espírito Santo, Santa Catarina and the Acre Territory) have less than 50 beds per hospital.

The report also gives a description of the plan prepared by the division of hospitals for cooperation with the states to develop progressively a network of hospitals needed in Brazil to improve health conditions. An important sum is set aside by the federal government this year to start the construction of small hospitals in the section where they are most needed.

Deaths

Louis Blanchard Wilson † noted pathologist and medical educator, died in Rochester, Minn., October 5, aged 76.

Dr. Wilson was born in Pittsburgh, Dec. 22, 1866, and graduated at the Pennsylvania State Normal School at California, Pa., in 1886. He taught biology in the Central High School, St. Paul, from 1888 to 1896, receiving in this year his medical degree from the University of Minnesota. He was associated with the Minnesota State Board of Health from 1896 to 1905, first as assistant and later assistant director of the bacteriologic laboratory, and for a time taught as assistant professor of clinical pathology at his alma mater.

In 1905 Dr. Wilson joined the Mayo Clinic to organize and develop its laboratories. When the division was subdivided in 1920 he became head of the section on general pathology. He had been director of the Mayo Foundation and professor of pathology of the Graduate School of the University of Minnesota from 1915 to 1937, when he became emeritus.

During World War I he was a major in the medical corps of the U. S. Army from January 1918 to June 1919, serving for fifteen months as assistant director of the Laboratory Division of the American Expeditionary Forces. He was promoted to the rank of colonel and in 1920 received the Distinguished Service Medal. To him goes a large part of the credit for the collection and preparation of pathologic specimens from the World War in the Army Medical Museum, Washington.

From 1917 to 1918 Dr. Wilson was chairman of the Section on Pathology and Physiology of the American Medical Association and from 1923 to 1931 member of the Association's Council on Medical Education and Hospitals. A specialist certified by the American Board of Pathology, Inc. and a former member of the National Board of Medical Examiners, Dr. Wilson held memberships in numerous societies including the Southern Minnesota Medical Association, the Association of American Physicians, the American Association of Pathologists and Bacteriologists, the American Association for Cancer Research, the Association of Military Surgeons of the United States, the Czech Medical Society of Prague and the Royal Academy of Medicine. He was also a member of the Minnesota Horticultural Society and the National Rifle Association and an honorary member of the American Society of Clinical Pathologists and the Alumni Association of the Mayo Foundation. He was president of the

Advisory Board for Medical Specialists from 1935 to 1937, of the Association of American Medical Colleges from 1931 to 1933 and of the National Society of Sigma Xi from 1932 to 1934. He was also chairman of the medical section of the American Association for the Advancement of Science from 1931 to 1932. In 1928 he had been ordered to active duty in the army medical department to serve on a commission conducting experiments in the ballistics of wound production. At the time of his death Dr. Wilson was senior consultant to the laboratories of St. Mary's Hospital, of which for many years he had been in charge.

Dr. Wilson was a respected leader in the field of graduate education in medicine. Calm judgment made him a most useful member of the numerous boards and committees on which he served. The fellowships, the library and the editorial sections of the Mayo Clinic testify to his interest in these fields.

William Osler Abbott, Wynnewood, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1928, assistant professor of medicine at his alma mater, where he had been associate in medicine, F. M. Kirby Fellow in surgical physiology, Smith, Kline and French Fellow in medicine, instructor in medicine and assistant instructor in pharmacology, assistant professor of medicine at the Graduate School of Medicine, University of Pennsylvania, member of the Medical Society of the State of Pennsylvania, American Gastro-Enterological Association, American Society for Clinical Investigation, Amer-

ican Clinical and Climatological Association, Philadelphia Physiological Society and the American College of Physicians, specialist certified by the American Board of Internal Medicine and diplomate of the National Board of Medical Examiners, began active duty as a major in the medical reserve corps of the U. S. Army in May 1942, attached to the 20th General Hospital, Camp Claiborne, La., and was honorably discharged because of physical disability in September 1942, associate attending physician at the Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York, served as physician in the gastrointestinal section of the medical clinic and assistant ward physician at the Hospital of the University of Pennsylvania, member of the editorial board of *Digest of Treatment*, aged 41, died in Wauquoit, Mass., September 10, of leukemia.

Edward William Wallace, Cranford, N. J., the School of Medicine of the Division of the Biological Sciences, University of Chicago, 1935, joined the University of Cincinnati College of Medicine as an assistant professor of pharmacology and later became an associate professor, on July 1, 1942 was given a leave of absence to serve as director of the toxicologic laboratories of Merck and Company, Inc., Rahway, formerly assistant in pharmacology and instructor at his alma mater, at one

time on the staffs of the National Institute of Health, Washington, D. C., and the Food and Drug Administration, received a grant from the National Advisory Cancer Council to carry on research on the endocrine relationships of cancer, received the doctor of philosophy degree from the University of Chicago in 1932, aged 34, died in Keyport, July 11, of a compound fracture of the skull and other injuries received when he fell from the mast of a boat.

William Bean Anderson † Brownwood, Texas, Vanderbilt University School of Medicine, Nashville, Tenn., 1888, Medical Department of Tulane University of Louisiana, New Orleans, 1894, one of the organizers and twice president of the Fourth District Medical Society of the State Medical Association of Texas, member of the American Academy of Ophthalmology and Otolaryngology, a charter member of the Texas Society of Ophthalmology and Otolaryngology, fellow of the American College of Surgeons, a founder, director and chief of the eye, ear, nose and throat department of the Medical Arts Hospital, served for many years as trustee of the Howard Payne College, aged 80, died, July 6, of coronary thrombosis.

Donald Cole Barber † Grafton, Ohio, George Washington University School of Medicine, Washington, D. C., 1930, served overseas during World

War I and was given several citations, including the Croix de Guerre from the French government and the Silver Star, first lieutenant in the medical reserve corps of the U. S. Army, not on active duty, aged 42, died, August 13, of coronary thrombosis.

George L. Barr, Owensboro, Ky., Hospital College of Medicine, Louisville, 1898, member of the Kentucky State Medical Association, on the consulting staff and for sixteen years a member of the board of trustees of the Owensboro City Hospital, now known as the Owensboro-Daviess County Hospital, aged 72, died, August 4, of prostatic hypertrophy.

Samuel Cushing Beach, Chicago, Rush Medical College, Chicago, 1892, consultant and industrial medical inspector, division of industrial hygiene, Illinois Department of Public Health, division surgeon of the Chicago, Burlington and Quincy Railroad at McCook, Neb., and the Illinois Central Railroad, aged 73, died, July 31, of complications following a fractured leg received in a fall.

Francis Everett Bedinger † Walton, Ky., Crichton University School of Medicine, Omaha, 1932, commissioned a first lieutenant in the medical reserve corps of the U. S. Army, October 1939, physically incapacitated for active duty, relieved from active duty in December 1941, aged 35, died August 2, of Hodgkin's disease.

LOUIS B. WILSON, M.D., 1866-1943

Edward Berninzoni, Denver, Regia Università degli Studi di Firenze Facoltà di Medicina e Chirurgia, Italy 1889, aged 78, died in the Mercy Hospital, August 4, following an operation on the prostate gland

S Price Blackwood, Corning, Ark (licensed in Arkansas in 1907), aged 57, died August 1, of pneumonia

George G Douglas, Elmwood, Neb., Missouri Medical College, St Louis, 1891, aged 80, died, July 16, of heart disease

Yervant S Elmadjian, Boston American University of Beirut School of Medicine, Syria 1914, aged 60, died, June 12, of coronary occlusion

William Kellogg Foote, Omaha, Chicago Homeopathic Medical College, 1893, aged 72, died, July 22

Daniel Reid Gunn, Memphis, Tenn., Memphis Hospital Medical College, 1910, aged 56, died, July 17, of cirrhosis of the liver

Thorne Sanford Harris, Shenandoah, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1927, assistant surgeon on the staff at the Locust Mountain State Hospital, aged 44, died in St Luke's and Children's Medical Center, Philadelphia, July 26

Notley William Hawkins ♂ Farmington, Mo Washington University School of Medicine St Louis, 1926, specialist certified by the American Board of Otolaryngology, served on the staff of the Bonne Terre Hospital, aged 42, died in the Barnes Hospital, St Louis July 27 of brain tumor

Samuel Edward Hudson ♂ Austin Texas Medical Department of Tulane University of Louisiana New Orleans 1886, on the staff of the Seton Infirmary, now known as the Seton Hospital consulting physician to the Southern Pacific Railroad, aged 82, died in the Brackenridge Hospital, July 1, of coronary occlusion

George M Jones, Springtown Texas (licensed in Texas under the Act of 1907), aged 76, died July 15, of heart disease and diabetes mellitus

Vincent J Keating ♂ Los Angeles, Chicago College of Medicine and Surgery 1909, past president of the Wyoming State Medical Society and the Sheridan County Medical Society, member of the medical board of the retirement fund of the city board of education on the staffs of the Queen of Angels Hospital and St Vincent's Hospital, where he died July 3, of atelectasis of the lungs following an operation for acute appendicitis, aged 58

Harry Lloyd McCarthy ♂ Los Angeles University of Pennsylvania School of Medicine Philadelphia, 1910, served on the staff of St Vincent's Hospital, aged 64, died, July 26, of heart disease

Mark Allen Newland, Center Point Iowa State University of Iowa College of Homeopathic Medicine Iowa City, 1892, member of the Iowa State Medical Society, aged 73, died, July 27, of arteriosclerosis

Huger Richardson, Loris, S C., Medical College of the State of South Carolina Charleston 1910, trustee of schools, aged 59, died, July 27, of heart disease

Daniel Scott Schenck, La Jara, Colo Jefferson Medical College of Philadelphia 1903, aged 61, died suddenly, July 1, of heart disease

Charles Robert Starkweather, West Cummington, Mass College of Physicians and Surgeons New York 1882, justice of the peace and member of the board of health, aged 95, died, June 18, of senility

Henrik Tillisch, Brookings S D Northwestern University Medical School, Chicago 1901, member of the South Dakota State Medical Association, senior member of the Brookings Clinic, president of the hospital board of directors of the Brookings Municipal Hospital since 1930, head of the student health service at the South Dakota State College of Agriculture and Mechanic Arts, aged 65, died, June 20, of coronary thrombosis

Emil S Tobie, Buffalo Université de Paris Faculté de médecine France 1888, member of the Medical Society of the State of New York, for many years on the staff of the Buffalo Hospital of the Sisters of Charity and the Deaconess Hospital, aged 80, died July 1, of pneumonia and myocardial failure

Harvey Ainsworth Tyler ♂ Chicago Rush Medical College Chicago 1889, at one time instructor of gynecology and obstetrics at his alma mater, formerly professor of gynecology at the Chicago Polyclinic, served as consultant to the woman's department of the House of Correction and as medical director of the House of the Good Shepherd, aged 74, died, July 3, of Doek's sarcoma

Robert A Van Allan, Rochester, N Y, Pulte Medical College, Cincinnati, 1885, died, July 8, of chronic nephritis, arteriosclerosis and chronic myocarditis

Dell Williamson Van Gilder, Cuyahoga Falls, Ohio, Rush Medical College, Chicago, 1900, veteran of the Spanish-American War and World War I, served on the staffs of St Luke's and St Anthony's hospitals, Denver, aged 65, died, July 14, of heart disease

Allison Moore Van Horn, Sea Breeze, N Y, Eclectic Medical Institute, Cincinnati, 1905, member of the Medical Society of the State of New York, aged 60, died, June 6, of terminal bronchopneumonia, hypertensive cardiovascular disease and diverticulitis of the sigmoid with pelvic abscess

James Heber Varnum, Benton Ridge, Ohio, Western Reserve University Medical Department, Cleveland, 1893, member of the Ohio State Medical Association, member of the board of education, aged 74, died, June 30, of arteriosclerosis

John Dillon Wakefield, Cincinnati, Miami Medical College, Cincinnati, 1893, served in the medical corps of the U S Army during World War I, for many years medical examiner for the Veterans Administration, aged 74, died, July 17, of cerebral hemorrhage

Frank Alfred Walsh, Erie, Pa., Jefferson Medical College of Philadelphia, 1895, member of the Medical Society of the State of Pennsylvania, fellow of the American College of Surgeons, past president of the Erie County Medical Society, served on the staff of the Hamot Hospital and for many years on the staff of St Vincent's Hospital, aged 76, died, July 29, of coronary thrombosis

Henry Smith Williams, Los Angeles, Chicago Medical College, 1884, assistant physician and pathologist to the State Hospital, Independence Iowa, 1887, assistant physician at the Manhattan State Hospital, New York, in 1888 and the Bloomingdale Asylum, New York, in 1889, at one time medical superintendent of the Randall's Island (N Y) Hospitals, author of numerous books, editor of "Historians' History of the World" in twenty-five volumes and "Works of Luther Burbank" in twelve volumes, aged 80, died, July 4, of arteriosclerosis

Will Reese Williams, Richlands Va Medical College of Virginia, Richmond, 1897, member of the Medical Society of Virginia, a member of the state board of Health, a director and first vice president of the Merchants and Farmers Bank, established in 1906 and the first and only president of its successor, the First National Bank, first president of the Richlands Rotary Club and for many years served on the town council, founder of the Grundy Hospital and the Mattie Williams Hospital, where he died July 17, of uremia, aged 70

Pearl C Wray ♂ Breckenridge, Texas, Gate City Medical College, Texarkana Ark 1906, formerly assistant health officer of Fort Worth and health officer of Kent County, for many years health officer of Breckenridge and physician for the Breckenridge High School football team, president of the Kent County Draft Board during World War I, recently medical examiner for the Selective Service Board, aged 65, died at a Fort Worth hospital, June 8, of heart disease

DIED WHILE IN MILITARY SERVICE

Edgar Fremont Haines ♂ Lieutenant Colonel, M C, U S Army, Chelsea Mass Boston University School of Medicine 1906 U S Army Medical School in 1933, commissioned a first lieutenant in the medical reserve corps of the U S Army in August 1909 and appointed a first lieutenant in the medical corps of the regular Army in August 1917, rose through the various grades to that of lieutenant colonel in April 1937, at one time professor of military medicine at the Boston University School of Medicine, member of the American College of Physicians, aged 60, died in the Tilton Hospital Fort Dix N J, July 22, of adenocarcinoma of the sigmoid

Edward Henry Herbert Old ♂ Medical Director, Captain U S Navy, retired Charleston S C University of Virginia Department of Medicine Charlottesville 1899, entered the U S Navy in September 1905 and retired in October 1940, retained on active duty as district medical officer of the Sixth Naval District, commanding officer of the U S S Solace, a hospital ship in World War I, and was awarded the Navy Cross for outstanding performance of duty, fellow of the American College of Surgeons, aged 66, died in the United States Naval Hospital July 1, of adenocarcinoma of the splenic flexure of the colon

HAIR LACQUER DERMATITIS

To the Editor—I was about to mail you a report on 4 patients with hair lacquer dermatitis of the neck, ears and face when I saw the notice in this morning's Philadelphia *Inquirer* that your office is aware of this condition. All these patients were seen within one month. Patch tests were positive in two of my patients.

The hair lacquer in all 4 of my patients was "Huber's," and two of the biggest department stores here, Wanamaker's and Strawbridge & Clothiers with whom I have been in contact, have removed this particular hair lacquer from sales.

I am awaiting a chemical analysis of the substance to send you a fuller report.

SIGMUND S. GREENBAUM, M.D., Philadelphia

CUTANEOUS ERUPTIONS FOLLOWING TOPICAL AND ORAL SULFATHIAZOLE

To the Editor—Dermatitis following local application of sulfathiazole has been the subject of four recent reports appearing in *THE JOURNAL*:

Livingood, C. S., and Pillsbury, D. M. Sulfathiazole in Eczematous Psoriasis: Sensitization Reaction to Successive Local and Oral Therapy. Report of Twelve Cases, Feb. 6, 1943, p. 406.

Cohen, M. H., Thomas, H. B., and Kalisch, A. C. Hypersensitivity Produced by the Topical Application of Sulfathiazole, Feb. 6, 1943, p. 405.

Weiner, A. L. Cutaneous Hypersensitivity to Topical Application of Sulfathiazole, Feb. 6, 1943, p. 411.

Shaffer, Bertram, Lentz, I. W., and McGuire, J. A. Sulfathiazole Eruptions: Sensitivity Induced by Local Therapy and Elicited by Oral Medication. Sept. 4, 1943, p. 17.

The authors have variously interpreted these phenomena either as contact dermatitis (dermatitis venenata) resulting from exogenous cutaneous hypersensitivity or as dermatitis medicamentosa resulting from absorption and endogenous hypersensitivity. It is also known that an individual may be sensitive to sulfathiazole in both of these respects and therefore that the two phenomena may be observed in the same individual. The matter is further complicated since sulfathiazole eruptions rather frequently follow oral administration of the drug and since local application may sensitize an individual to subsequent oral or parenteral administration. In such instances there need not necessarily have been a dermatitis at the time of the original topical application, but if this has been present the dermatitis following ingestion of the drug may appear initially and more severely in the formerly affected sites. Finally, attention has been called to the tendency of sulfathiazole eruptions so induced to mimic the preexisting dermatosis for which treatment was initially intended.

It follows that contact dermatitis from topical application of sulfathiazole can be established by means of patch testing. In dermatitis medicamentosa following oral administration or following absorption from topical application one would expect to find negative patch tests but positive passive transfer reactions (Prausnitz-Kustner). This was recently demonstrated in an article by Shaffer, Lentz and McGuire.

This dual ability of sulfathiazole to cause both dermatitis venenata and dermatitis medicamentosa either from ingestion or from cutaneous absorption is by no means unique. It is seen also with quinine and mercury and other drugs employed therapeutically by ingestion or injection and by local cutaneous application.

It is my opinion that physicians other than dermatologists may not have a clear understanding of the several mechanisms involved in the production of sulfathiazole eruptions by local

and oral administration. The various clinical reports have failed to emphasize these differences. The popularity of sulfathiazole therapy indicates that a clearer conception of the aforementioned processes might be of value in the management of and prevention of recurrence of cutaneous hypersensitivity to sulfathiazole.

Assistant, Department of Dermatology, University
of Cincinnati College of Medicine

SOUTH CAROLINA MEDICAL STUDENTS ON THE WAGNER-MURRAY- DINGELL BILL

To the Editor—The students of the Medical College of the State of South Carolina in discussing the Wagner-Murray-Dingell bill have decided that it is a treacherous piece of legislation and that it would not only shackle the medical profession but lead to totalitarianism.

A meeting of the student body was called on August 13, at which time the following resolution was unanimously adopted: "We, the medical students of the Medical College of the State of South Carolina, assembled for the purpose of discussing the Wagner-Murray-Dingell bill (U. S. Senate bill No. 1161) now introduced in congress, are alarmed at the obvious intention to establish state operation of medical services in such a totalitarian fashion under the sole direction of one person."

A committee to outline and initiate action against the bill was formed and immediately began to function. Brief outlines of the bill were written together with letters to be sent to the families and friends of the students informing them of the contents of the bill and urging them to write their congressmen about it. Articles were written to the newspapers of this area for publication, and conspicuous cooperation was received from the editors. To this method of publicity were added several radio speeches by prominent men. Every medical college in the country was informed of our intent and actions. Pleasingly enough, those replies we have received were in full accord with our views.

The efforts of the students came to the attention of the Army and Navy authorities, who immediately ordered the members of the armed forces taking part to cease, as no member of the armed forces is allowed to participate in any activity which has to do with government policy. This order resulted in the cessation of a great deal of the activity on the part of the students, since the vast majority are members of the armed forces, however, those of us who still retain civilian status are going ahead with the original program.

The efforts we made toward publicizing this bill have met with a great deal of success. The editors of the newspapers here and over the rest of the state have become interested and carried on with spontaneous editorials. The radio presentations were accepted by the public with enthusiasm, and the interest of the public manifested itself through letters to their congressmen and to the editors of the various papers, all letters have been in accord with our views. Even the clergy in this area have contributed in this manner.

These procedures have brought excellent results. The congressmen of this area have publicized their opposition to the bill and stated that they will not only vote against it but will do all in their power to prevent it from reaching the floor of Congress.

We believe that our actions have been to some degree responsible for these results, we urge that similar action be taken by the profession and other civilian medical students.

MEDICOLEGAL ABSTRACTS

Taxes Hospital Service Plan Corporation Not a Corporation Organized and Operated Exclusively for Charitable Purposes—The Associated Hospital Service Corporation of Massachusetts was incorporated under a Massachusetts statute authorizing the organization and operation of "corporations for the purpose of operating a nonprofit hospital service plan whereby hospital care may be provided for subscribers to the plan under contracts which entitle subscribers to certain hospital care." The corporation entered into contracts with subscribers which entitled them on the payment to the corporation of a specified annual subscription fee stated hospital care when necessary, to be rendered by so-called hospital participating members of the corporation. The corporation in turn agreed to pay the hospitals rendering that care on a specified scale. If there was a deficiency in any one year subscribers were not to be assessed to meet the deficiency but the participating hospital members were to suffer a pro rata deduction in payments to be made them during the ensuing year. The corporation brought suit in the district court of the United States for the district of Massachusetts against the local collector of internal revenue to recover taxes paid by it under protest alleged by the collector to be due under the taxing provisions of the federal social security act. The taxing provisions of the federal social security act specifically exempt from the payment of those taxes "a corporation organized and operated exclusively for charitable purposes."

no part of the net earnings of which inures to the benefit of any private shareholder or individual." The corporation claimed that it was such a corporation and consequently was exempt from the payment of those taxes. From a judgment in favor of the corporation the collector appealed to the circuit court of appeals, first circuit.

If, said the circuit court of appeals, the plaintiff corporation is a corporation organized and operated exclusively for charitable purposes it is exempt from the tax provisions of the social security act. The plaintiff corporation maintains that it is such a corporation since its object is the promotion of health its deficiencies are not assessed on subscribers nor its earnings divided among them, any surplus created is to be used to reduce rates or increase services in the future and the principal officers of the corporation serve without compensation. We cannot accept the plaintiff's argument. In our opinion the corporation is being conducted more on a business than on a charitable basis. The payment of a fee is a prerequisite to the receipt of benefits and the relationship existing between the corporation and the subscriber is contractual. The subscribers consider themselves neither charitable donors nor the recipients of charity. The corporate capital is not composed of charitable contributions but of fees exacted from subscribers. Without the subscription payments the corporation could not function. Membership is not limited to the needy but as a matter of fact is composed largely of the middle class and well to-do. It is difficult to distinguish the plaintiff corporation from a mutual insurance company or an employee benefit plan. Here we

have what is essentially a business arrangement under which a group of people have banded themselves together to purchase at rates as low as possible hospital care in the event of sickness or accident. These rates are subject to approval by the Massachusetts Commissioner of Insurance. Such a corporation is not charitable. While the charging of fees does not necessarily render an institution noncharitable, still the plaintiff corporation exacts a fee as prerequisite to the receipt of benefits in every case. This is not true of the ordinary charitable organization. Many charitable (educational) institutions charge fees, but they do not require payment in every case and ordinarily the fee bears no precise relation to the cost of the benefit conferred.

The plaintiff contended that it was different from the ordinary mutual insurance company in that it does not make assessments on its subscribers for the payment of deficiencies nor does it divide any surplus among them by way of dividends. The fact answered the court, that it meets deficiencies out of future subscription fees and uses its surplus to reduce rates or increase services for future members is not sufficient to make the plaintiff a charity. The mutual insurance company returns at least some of its surplus for the benefit of future members. This partial retention of surplus does not render a mutual insurance company a charitable organization. The mere fact that the plaintiff retains its entire surplus for the benefit of future members is not sufficient to make the organization a charitable one. The plaintiff further contended that the main distinction between it and a mutual insurance company is that any surplus which the plaintiff may have on liquidation must be devoted to some charitable purpose, whereas the surplus of a mutual insurance company on liquidation will be divided among the members of the company. This, said the court, is not enough to make the plaintiff charitable. It is extremely unlikely that there will ever be any surplus to liquidate. So long as the corporation is successful it will continue to operate. If it is not successful there will be no surplus. We do not feel that a corporation should be classified as a charity on the basis of a contingency unlikely to happen. Moreover, the subscribers responsible for the creation of the surplus do not act out of any charitable motive but pay their subscriptions solely on a business basis with full knowledge that if there is any surplus in a particular year they can become members in the following year and get the benefit of the reduced rates or increased services resulting from the surplus.

That Congress did not intend organizations similar to the plaintiff to be considered corporations organized and operated exclusively for charitable purposes, continued the court, is borne out by a careful examination of the statutes. The subsections of the social security act the construction of which are here involved are exactly the same as subsection 6 of section 101 of the internal revenue code, which exempts such corporations, among others, from income taxation. The exempting section of the income tax law, however, differs from the exempting sections of the social security act in one important respect. In addition to the exemption granted to corporations organized and operated exclusively for charitable purposes, the income tax law in other subsections of section 101 also grants exemptions to certain types of mutual savings banks, fraternal beneficial societies, cooperative building and loan associations and banks, cooperative cemetery companies, voluntary employees' beneficial associations and a number of other similar organizations. Not one of these specific exemptions is contained in the social security act. The fact that Congress specifically mentioned these organizations, even though the statute contained the exemption granted to corporations organized and operated exclusively for charitable purposes, would seem to indicate that Congress did not consider these organizations specifically mentioned to be within the scope of a charitable organization. Since the plaintiff closely resembles many of the organizations specifically exempted, Congress could not have intended it to fall within the scope of a corporation organized and operated exclusively for charitable purposes.

The Massachusetts statute authorizing the formation of corporations such as the plaintiff describes the corporation as "charitable and benevolent" and exempts it from taxation. An act was passed also in the District of Columbia by the Congress authorizing the organization of similar corporations in the District and exempting them from taxation as "charitable and benevolent." The plaintiff relied on these two statutory designations as binding with respect to classifications for the payment of federal taxes. But, said the court, it appears to be clear that both the Massachusetts legislature and Congress were desirous of exempting such organizations from local taxation even though they felt that these organizations were not charitable in the ordinary sense. If they were charitable organizations in the accepted meaning, there would have been no need by statute to describe them as charitable and specifically to exempt them from taxation. The Massachusetts statute designating the plaintiff corporation as a "charitable and benevolent" corporation is important here so far as it affects the rights, duties and powers of the plaintiff corporation. We consider the characteristics of the plaintiff as established by state law, particularly its power with respect to surplus. Beyond that, state nomenclature is not binding on us. As was said by the Supreme Court of the United States in *Morgan v Commissioner*, 1940, 309 U. S. 78, 60 S. Ct. 424:

State law creates legal interests and rights. The federal revenue acts designate what interests or rights, so created shall be taxed. Our duty is to ascertain the meaning of the words used to specify the thing taxed. If it is found in a given case that an interest or right created by local law was the object intended to be taxed, the federal law must prevail no matter what name is given to the interest or right by state law.

We have concluded that the plaintiff corporation has not the characteristics of a charitable organization in the ordinary meaning of the term. The fact that the Massachusetts law labels it a charity and that Congress labels a similar plan in the District of Columbia a charity would also seem to be unimportant.

The judgment of the district court in favor of the plaintiff corporation was reversed and the cause remanded.—*Hassett, Former Acting Collector of Internal Revenue, v Associated Hospital Service Corporation of Massachusetts*, 125 F. (2d) 611 (1942).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1933 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Experimental Production of Gastric Ulcers with Pitressin—Nedzel injected into young dogs intravenously 20 pressor units of pitressin for every 5 kilograms of body weight. His observations pointed to a conditioning of the blood vessels as the immediate cause of ulcer formation. Pitressin injected intravenously provokes a spasm of the small blood vessels as well as a spasm of the muscular tissues, which in their turn add to the compression of the blood vessels. The contraction is later followed by dilatation of the same blood vessels. A normal biologic rhythm of this type keeps the vascular supply and demand in constant equilibrium, but the same contraction whether due to changes in the blood vessels or to contraction of the extrinsic muscles, if prolonged or exaggerated, injures the parenchymal cells, because it will be associated with undue general or local anoxia. The greater the discrepancy between the demand for oxygen and the supply, the greater the changes which will follow. With the pressor phase as it occurs under natural conditions of life (e g with cold, with relative alkalosis, with sympathicotonia) or after injections of pitressin, contractions of the blood vessels occur which may reach such a degree that a vessel may rupture and establish a hemorrhage directly into the stomach. Small hemorrhages and foci of necrosis can be observed in the mucosa and dilated blood vessels in the submucosal and muscular layers. An exudate containing fibrin and formed elements which have passed through the undamaged epithelial layer may collect on the surface of the mucosa. Erosions, edema of the wall of the stomach, necrosis of the mucosa associated with an increased number of mononuclear cells, healing of the erosions and ultimately typical ulcer formation may be discerned. Persons subject to ulcer formation are usually asthenic with labile nervous and vascular systems. The disease is seasonal and occurs mostly in the northern latitudes. It is likely that during the late winter and spring there is a greater tendency toward inflammatory reaction and toward digestion of tissue. Animals which have been fatigued and are more acid, and thus biologically weaker evince greater autonomic difficulty in adjustment to meteorologic changes and in them superimposed pressor effects from injections of pitressin apparently lead more readily to prolonged spasm and to delayed recovery from the effect of spasm.

Losses of Vitamin During Storage of Dehydrated Vegetables—Tressler and his associates studied the carotene, thiamine and ascorbic acid contents of rutabagas, beets, cabbage and potatoes during commercial dehydration and subsequent storage under controlled conditions. Prior to storage the dehydrated vegetables were packaged (1) in glass containers, (2) under carbon dioxide in glass containers or (3) in either moisture proof cellophane or ploxifilm bags. Storage temperatures employed were —40, 33, 58 and 75 F. Little carotene was lost from any of the vegetables during dehydration, but the loss of this vitamin was relatively rapid at all storage temperatures above —40 F. Storage under carbon dioxide helped to prevent rapid loss. Some thiamine is dissolved out during hot water blanching. Subsequent storage caused no further loss. Potatoes lost nearly all of their ascorbic acid content during blanching in hot water and subsequent dehydration. The fresh beets contained a relatively small amount of ascorbic acid. About one third of this was lost during precooking and subsequent dehydration. The resultant product was not a good source of vitamin C. Rutabagas lost approximately 85 per cent of their ascorbic acid during water blanching and dehydration. The remainder was fairly well retained at the lower storage temperatures, but at either 58 or 75 F more than half is lost in four months. Storage under carbon dioxide had little effect in retarding the rate of loss during storage. Cabbage retained its vitamin C content better than any other vegetable during dehydration and subsequent storage. That tested was high in vitamin C containing more than 3 mg of ascorbic acid per gram of dehydrated cabbage.

Gastric Herniation at Esophageal Hiatus—In reviewing the incidence of hiatus hernia among 1500 upper gastrointestinal examinations Turner found a frequency of 35 per cent. Hiatus hernia is least frequent in males and nulliparous females.

under 30 years of age. Most cases occur in well nourished persons past middle age. Like diverticulosis, gastric herniation at the esophageal hiatus may exist without symptoms but, like diverticulitis, it may assume great significance in certain cases. The decided difficulty which sometimes occurs in distinguishing this condition clinically from gallbladder disease and from coronary disease in particular contributes to its importance. The hematemeses and the type of pain are often clinically suggestive of cancer but not likely to be confused with peptic ulcer. Timely recognition of hiatus herniation may avoid a needless cardiac regimen or unnecessary surgical procedures. Estimation of a degree of gastric constriction which occurs at the hiatus, estimation of mobility of the stomach in relation to the hiatus and attention to the rugal pattern in the herniated portion of the stomach are of paramount importance. Mobility and the degree of constriction should be estimated because of the relation of incarceration and adhesions to symptoms. The observation of the barium filled stomach in the supine patient during the Muller effort (in which the patient inspires with closed passages after complete expiration) is suggested as an aid for study of functional caliber of the hiatus. Fluorographic and other methods of complete x-ray demonstration of mucosal pattern in the herniated portion of the stomach deserves more attention because of the association of mucosal congestion with symptoms. A broadly dilated esophageal hiatus with a freely mobile and distensible herniating portion of stomach and normal rugal pattern is least often connected with symptoms. Conversely, a portion of stomach persistently herniated at the hiatus with no mobility, limited distensibility and definite prominence of rugal pattern is most likely productive of symptoms. Large abdominal tumors or large accumulations of ascitic fluid or both may cause herniation of the stomach by increase in intra-abdominal pressure.

Primary Gonorrheal Cutaneous Infection—Lowry and Franks report the occurrence of an eruption on the shaft of the penis of a man aged 33 thirty-five days after exposure to a prostitute. The eruption was associated with pruritus and burning and was elevated, hard and papular. Later the hard lesions became soft and some pus oozed from them. After admission to the hospital a new lesion developed posterior to the existing eruption. There were four discrete lesions 0.5 cm in diameter involving the ventral portion of the midshaft of the penis. The Kahn and Wassermann tests were negative. Repeated darkfield examinations of the material from the lesions were negative for *Treponema pallidum*. No Ducrey organisms were found. Many gram negative intracellular diplococci morphologically consistent with gonococci were found on repeated examinations. Material from a pustule on the shaft of the

penis produced gonococci in pure culture. Local applications of boric acid solution dressings were applied to the lesions. A routine course of sulfathiazole therapy was ordered. Soaks of potassium permanganate (1:8,000), also 2 per cent urea solution and sulfathiazole powder, were used over an adequate period of time without obvious improvement. Gentian violet and scarlet red dyes were applied to the lesions without benefit. After all chemotherapy had failed, the Davis-Bovie coagulating current was used for the excision and cauterization of the pustular lesions. The treated areas healed slowly. This case is noteworthy because gonorrheal infection involving the skin of the penis in the absence of gonorrheal urethritis has not been previously reported.

Transfusion Unit in 700 Bed Hospital—Erf and Jones discuss the clinical experiences and the practical problems associated with the blood transfusion plasma unit of Jefferson Hospital for the year ended July 1, 1942. During this year 3,857 bottles of blood, each with approximately 500 cc, were withdrawn from 3,906 donors. "Out dated" bottles of blood, 1,177 in number, were centrifuged and the plasma removed. The plasma was frozen by the adtevac process. The blood transfusion unit issued 2,869 blood transfusions, 32 per cent of which were followed by reactions, and 695 plasma (dried) infusions, 0.14 per cent of which were followed by reactions. The reactions were classified as (1) chills without fever, (2) chills with fever, (3) urticaria and (4) incompatibilities. The pyrogenic reactions, or chills with fever, were most frequent. It is assumed that many of the pyrogenic reactions were due to circulating foreign proteins in the recipient. Since the percentage of reactions was much lower following plasma infusion, it must be assumed that the red blood cells of the transfused blood are the agents that react with the circulating foreign proteins of the recipient. Dried human plasma will ultimately be the agent universally used in shock. Concentrated plasma almost invariably causes hemodilution and a rise in blood pressure. When plasma must be given in tow holes on a rollup battleship or ambulance or in civilian emergencies, long rubber tubes and drip bottles cannot be used conveniently. But 10 or five fold concentrated plasma obtained by injecting with a 50 cc syringe of 40 cc of distilled water into a vial containing 16 Gm of plasma (the amount present in a pint of blood) can be administered intravenously or intrasternally within a few minutes. The necessary equipment for the administration of concentrated plasma can be carried in a coat pocket and weighs only 1 pound. Concentrated plasma can be given to dehydrated patients without harm. Intrasternal and intracardiac (intrasternal and the like) of administering blood or plasma have been life saving in the authors' experience.

Chronic Seasickness—Schwab examined 115 naval personnel with chronic seasickness severe enough to bring them to the hospital. He found that 50 per cent of these men showed abnormalities in the gastrointestinal tract. These were detected by barium fluoroscopy, which demonstrated (1) irritability of the pylorus and duodenum with a resulting pylorospasm, (2) increase in gastric secretion even with fasting, (3) some increase in the gastric rugae and (4) loss of peristalsis. These conditions persisted in some patients for three or four weeks gradually becoming less pronounced and in 1 case nearly disappearing after three months. Different diagnoses mask the actual incidence of seasickness. The reason for this is that being seasick is considered as something of a weakness or a disgrace. Therefore medical officers and pharmacists, mates out of kindness, will often give to the seasick sailor a diagnosis such as psychoneurosis, gastric neurosis, gastric ulcer, gastritis, headache, sinus disease, appendicitis or back strain. A large percentage of persons subject to seasickness show neurotic trends. A man with pronounced nausea, vertigo, headache, vomiting and apprehension and discouragement is not as able a man as his unaffected fellow. This difference in ability is not easy to measure, but it involves alertness, skill, temper, resistance to infection, cold, heat and immersion. The condition is not to be disregarded, since it has a definite military bearing. The situation is to try to keep out of the service those individuals suffering from chronic motion sickness in the past, and these can be picked by a questionnaire. Those found in the service should be sent to shore jobs if their abilities warrant their retention in the service.

Joint Pains Caused by Sterile Streptococcus Toxin—Rhoads and Afremow investigated the health of a group of student nurses who had multiple joint pains as a reaction to one or more immunizing doses of scarlet fever toxin. They were considered particularly suitable subjects because they are frequently exposed to hemolytic streptococcus infections. During the years 1934 to 1940 a group numbering 181 was found to have reported this reaction. Their health records were carefully tabulated. An equal number of nurses who were similarly immunized but reported no joint pains as a reaction to the doses were chosen from the records of each year as a control group. The observations support the view that sensitiveness to a hemolytic streptococcus toxin is present in a high proportion of persons who have had rheumatic infections or who harbor chronic streptococcal infection which is not present in other persons. It is manifested by joint pains when streptococcus toxin is introduced into their tissues. Such persons appear to develop rheumatic disorders such as heart disease, polyarthritis and erythema nodosum more frequently than other persons not similarly sensitized.

Gold Therapy in Rheumatoid Arthritis—Price and Leichtenritt present an analysis of gold salt therapy in 101 roentgenologically studied cases of rheumatoid arthritis. For an evaluation of late results a follow-up study on 81 available subjects of this series is included. Gold sodium thiomalate (myochrysine) was used in 91 cases and gold thioglucose (solganol-B oleosum) in 10. Gold sodium thiosulfate was used in 2 cases to complete courses started with myochrysine. The sodium thiomalate and thioglucose preparations were given intramuscularly, gold sodium thiosulfate intravenously. Gold is an effective remedy for the treatment of rheumatoid arthritis, aiding in the alleviation of joint symptoms and effecting rehabilitation in a significant percentage of patients. Aurotherapy should be limited to rheumatoid arthritis. It is most effective in the early stages of the disease. It is frequently effective in relieving pain and stiffness in advanced cases and is therefore worthy of a trial in these. Careful and repeated follow up observations should be made before drawing final conclusions, since there is a high incidence of relapse and remission in the natural course of rheumatoid arthritis. Gold is a toxic drug and should be used only by those having experience with it. The toxicity is probably the result of individual drug sensitivity rather than of intoxication caused by a heavy metal. The administration of 7 to 9 Gm of a gold salt without the development of toxic reactions would tend to support this contention. The exact mode of action of the gold preparations is not known.

Experiences with Battle Wounds of Head—Money and Nelson review observations on 78 cases of all types of head wounds which were treated between July and December 1942 during the fighting in the vicinity of El Alamein. The thoroughness of the initial examination and toilet of the wound is more important than the time factor, at least up to four days as long as prophylactic sulfonamide therapy is maintained during the period of waiting. Surgeons with field surgical units must have a knowledge of neurosurgical technic and be provided with adequate facilities if this class of wound is to be correctly dealt with in forward areas. It is better to stabilize these facilities at a place where the patients can be held after operation, and so arrangements should be made to transport the patient back as rapidly as possible, preferably by air ambulance to a special center. An alternative plan is the provision of a field surgical unit with operating theater and beds entirely on wheels which can keep pace with the advancing or retreating troops or be replaced by another similar unit when its accommodation is filled. The removal of indriven bone fragments and inorganic debris is more important than the extraction of metallic foreign bodies. Even minute missiles making a small wound in the scalp and outer table of the skull, are likely to drive large comminuted pieces of the inner table deeply into the brain and cause more extensive damage than the size of the missile and the condition of the patient would indicate. Closure of the tear in the dura mater should be attempted in order to prevent the formation of hernia cerebri, cerebrospinal fluid fistula and aerocoele. The actual concentration of sulfonamide in the cerebrospinal fluid of every patient varies with the same dosage and must be checked at frequent intervals by colorimetric methods to make sure an adequate concentration is being attained and maintained in case of intracranial infection.

Communications Between Coronary Arteries Produced by Inflammatory Agents—Schildt and his collaborators proved experimentally that trauma applied to the surface of the heart brings about the development of communications between one coronary artery and another. The trauma was produced by abrasion of the surface of the heart. The authors attempted to find a substance which, when applied to the heart produces the same effect. Various substances were introduced into the pericardial cavity of dogs through a small opening in the parietal pericardium which was then tightly sutured. The pericardium was opened at the end of one, two and three weeks under surgical conditions. Inter coronary communications were determined by a special method. Among the substances investigated were croton oil, oil of sandal, formaldehyde, acriflavine, typhoid vaccine, sodium morrhuate, sodium ricinoleate, iodized and chlorinated oil, tragacanth, magnesium silicate, silicon, water glass, agar, cotton gauze, a mixture of boric, aluminum and starch, dried human skin and asbestos. Silicate in the form of powdered asbestos produced the most favorable reaction. It

caused the development of new communications between one coronary artery and another, it reduced the mortality following ligation of a coronary artery, and it reduced the size of the infarct which develops after the coronary artery has been ligated. The application of asbestos to the surface of the heart is a safe surgical procedure in animals provided a dose of about 0.1 to 0.2 Gm is used rather than larger doses. Inflammatory agents used on the heart may not be without harmful side effects and they should not be used indiscriminately.

Convulsions During General Anesthesia—Ray and Marshall report 12 cases in which convulsions occurred out of a total of about 75,000 subjected to general anesthesia during the past ten years at the New York Hospital. Convulsions occur in about 1 in 6,000 patients subjected to general anesthesia. The mortality rate is 25 per cent—too high to be the result of convulsions alone. The term 'other convulsions' is misleading, since the convulsions may occur during other types of general anesthesia. Most of the alleged causes of the convulsions are not of a nature to be alone or directly responsible, but most of them bear some relationship to the delivery, transportation and utilization of oxygen for tissue respiration, thus suggesting anoxia as the chief factor in precipitating the convulsions. Since the cells of the brain are more sensitive to anoxia convulsions often appear before other signs, but when the convulsions do appear in advanced state of anoxia may already exist. The incidence of convulsions during anesthesia may be lowered by attention to the preparation of the patient for operation, to the proper administration of the anesthetic and to the contributing effects of the operation itself. When convulsions do occur it is advisable to discontinue the anesthetic, to terminate the operation as quickly as possible, to administer oxygen, to correct any unfavorable position on the operating table, to keep the airway open (bronchoscopic aspiration may be required in case of atelectasis), to give some form of soluble barbiturate intravenously to control the convulsions, such as sodium amital, sodium phenobarbital or pentothal sodium, to replace blood or fluid loss, and to allay hyperthermia by sponging the body or irrigating the rectum with cold water. An oxygen tent provides the dual service of cooling and supplying adequate oxygen. There may be advantage in administering hypertonic dextrose solution intravenously, particularly to combat unrecognized hypoglycemia, and intravenous calcium gluconate or intramuscular parathyroid injection to correct calcium imbalance.

Primary Tuberculosis of Conjunctiva—Sitchevskaya and Sedam report the occurrence of primary tuberculosis of the conjunctiva with complete recovery in a child 18 months old. The diagnosis of primary tuberculosis was made because (1) a lesion was not present in any other organ of the body, (2) the process was unilateral and (3) there was involvement of the preauricular and other regional lymph nodes, which according to Ranke is typical of the primary complex. The source of the

infection was not certain. Tubercle bacilli were found in the smear and culture of pus from the preauricular lymph node and in excised tissue from the conjunctival lesion. The taking of a specimen from the conjunctiva for biopsy apparently acted as a therapeutic measure, as the eye improved rapidly after the biopsy. The suppurated lymph nodes responded well to aspiration and several fractional doses of x-rays. The outcome was favorable, which is in accordance with the results obtained in the majority of cases reported in recent years.

Keratoconjunctivitis Sicca—Gifford and his associates observed during the past four years 49 patients with evidence of deficient lacrimation. They divide these patients into three groups. Group 1 comprised 16 patients showing a lacrimal deficiency with moistening of less than 15 mm on the Schirmer test after five minutes, but no corneal or associated changes. Group 2 contained 21 patients who showed fairly severe lacrimal deficiency with corneal and conjunctival changes of such a degree as to be visible only with the slit lamp and as a rule no associated signs. Group 3 comprised 12 patients showing the typical Sjogren syndrome, with almost no lacrimal secretion on Schirmer's test, pronounced corneal and conjunctival changes, and one or more of the extraocular signs of that syndrome, usually a deficiency of salivary secretion. The diagnosis of Sjogren's syndrome presents no difficulties. A dry, ropelike secretion with shreds adhering to the corneal epithelium is seen in practically no other condition. Filaments may be seen, and staining with fluorescein will usually show a few areas large enough to be seen grossly. The slit lamp will show many more staining areas. The conjunctiva appears dry, red and more or less thickened. In extreme cases it is so thick and velvety as to suggest trachoma. The associated symptoms and examination of the mouth will clinch the diagnosis. It is the mild forms which present difficulties in diagnosis. These forms may easily be diagnosed as chronic conjunctivitis. Slit lamp examination, after staining with fluorescein, will reveal corneal changes. The fact that patients were seen with definite lacrimal deficiency but no corneal changes indicates that some other factor may be necessary to produce the typical picture. A diagnosis of keratoconjunctivitis sicca in its milder forms depends on a knowledge that these mild forms exist and on the routine use of a test for lacrimal function whenever the possibility of the condition exists. The patients in group 1 seemed to obtain relief from irritation by the use of a substitute for tears. The authors have found the use of gelatin and Locke's solution, as proposed by Rucker, satisfactory, provided a preservative is added to prevent bacterial growth. Patients such as those in group 2 will often obtain enough relief when using this solution so that nothing further is necessary. Patients showing a more severe deficiency and more corneal lesions obtain only relative relief and are much more comfortable when the tear points are closed. Patients with moderate lacrimal deficiency were given subcutaneous injections of 0.5 mg of prostigmine hydrobromide. Of 13 patients so treated, 11 showed a definite increase in lacrimal secretion. Since most patients in groups 1 and 2 obtained relief from a substitute for tears and those with more severe manifestations from closing of the tear points, no attempt has been made to treat a series of patients for long periods with prostigmine. Amounts of vitamin A were added to the diet of a number of the patients. Since this supplementary treatment was usually begun along with other treatment, it was difficult to judge its effect. The patients of group 3 obtained only relative relief of symptoms by a substitute for tear. Closure of the tear points, however, always produced improvement.

Heparin in Thrombosis of Retinal Vein—Reports in the literature indicate that treatment with heparin gives excellent results in thrombosis of the central vein of the retina if instituted early. The 2 cases described by the authors are interesting because of the length of time during which the thrombosis existed before treatment (in 1 case five weeks and in the other three weeks) and because of the exceptionally good visual results obtained (vision of 6/6). These were cases of true occlusion of the central retinal vein and not of branch vein. The results obtained indicate that thrombosis of long duration

is also amenable to heparin treatment. The reason is difficult to understand. It may be that heparin prevents further increase in the thrombotic process, thus permitting greater canalization and resumption of the normal function of the vein.

Conjunctival Exanthem in Spotted Typhus—Axtsin observed red points and spots in conjunctivas of persons dying of typhus. This sign received scant attention and is practically unknown to the majority of the physicians. It was found in 94 per cent of the cases of typhus investigated at the Moscow Clinical Institute for Infectious Diseases. In 95 per cent of these cases the cutaneous eruption was indistinct, in 12 per cent it was absent. The conjunctival spots remained the sole distinguishing sign on gross inspection. In 6 per cent of undoubted cases of typhus, gross inspection failed to reveal these spots. The conjunctivas in these cases appeared pale. Such cases belonged to a group in which death took place late in the disease and was caused by various complications, such as pneumonia or reactivated pulmonary tuberculosis. The red points and spots present various forms and dissimilarities as regards the intensity of their bright red or yellow color. They are seen on the conjunctiva of the lower lid, on the upper lid and occasionally on the sclera. In more than 600 cadavers conjunctival spots were encountered with fair constancy in only the following infectious diseases: (1) typhus, (2) septic endocarditis, particularly endocarditis lenta, and (3) meningococcal sepsis. Exceptionally, red spots were noted on the conjunctivas in pneumococcal sepsis complicated by purulent meningitis. Other infectious diseases only rarely present similar changes. The finding of these characteristic changes in the conjunctivas of cadavers justifies the suspicion of typhus in clinically obscure cases.

Spontaneous Rupture of Normal Spleen—Spontaneous rupture of a previously normal spleen is a rare lesion the exact incidence of which is difficult to determine. A certain amount of suspicion is always attached to the diagnosis because the spleen may not have been normal previously and because the elimination of the possibility of minor trauma is difficult. Brines suggests the following definition for the term: the spleen is found to be free from disease on careful pathologic examination and there is no history of injury other than movements or physiologic strains which are a part of the daily life of the average person. He lists 35 cases collected from the literature and a detailed history of a new case.

Cancer Family—Wood and Darling present the record of a cancer family in which bilateral carcinoma of the breast had occurred in four generations. Attention was drawn to this family during a study of the third generation. These were 3 sisters, all of whom had breast cancer. One female sibling of the fourth generation developed a breast cancer at the age of 18 years. The predisposition to cancer of the breast seems to be transmitted in the maternal line of descent. Breast cancer occurred only in those women who had been nursed by their mothers. Mammary glandular tissue in all cases examined microscopically was hyperplastic and compatible with the changes induced by hyperestrogenization. In view of the hyperplastic breast tissue and the rather singular nursing history, the operation of a factor somewhat similar to that demonstrated by Bittner in mice is suspected. A cancer family with 5 sisters afflicted with mammary carcinoma, in 3 of whom the disease was bilateral, was recently reported by Handley. In 2 of these patients there were changes described as "chronic mastitis," which in one was proliferative in type. When it is discovered that a patient is a member of a family such as the one just presented or that cited by Handley, the question of early recognition of the disease as well as possible prophylaxis becomes pertinent. The authors pose the following questions: Should a program of "wait and see" with periodic examinations be recommended? Should surgical excision of the breast be done? Should one rely on administration of antiestrogenic hormones or castration? Will it be possible to recognize in the future a syndrome indicative of hyperestrogenization or other syndromes that might serve as danger signals. Should these women have babies? If so should they nurse them and if not, should they run the danger of breast carcinoma from stagnation?

Allergic States in Selectees—A study of the relationship of allergic states to the socioeconomic background has been made at the Boston Recruiting and Induction Station. In 60,000 consecutive examinations of selectees 495 were disqualified for general military service because of severe allergic states. The total rejection rate was high in the semirural areas, was lowest in the one family residential districts and rose again steadily to its peak in the registrants from crowded tenements. The rejection rate for neurocirculatory asthenia, used as a control, showed no significant variation from one community to another, regardless of socioeconomic aspects. The prevalence of disqualifying allergic states was constant in many socioeconomic backgrounds, but there was a definitely increased prevalence of severe allergic states in semirural communities and a greatly decreased rate in crowded tenement districts. The low incidence of allergic states in the poor, overcrowded tenement areas tends to confirm the opinion of Beard, Bostock and Phoebus that the poor are less likely to have allergic conditions, but as this low rate appears only in the very poor of the slum tenement areas and not in poor semirural areas it suggests that the incidence of allergic states is not related to poverty per se. It does, however, seem logical to explain the variations in prevalence largely on the basis of exposure to air borne allergens, for a person living in a semirural region is in more direct contact

with more plant and animal emanations than the tenement dweller, surrounded by high buildings and pavements. Furthermore, the consumption of highly antigenic foods (milk, eggs, fish, meats, chocolate) is higher in rural and better class areas than in poor tenement areas. The hereditary nature of allergic states seems well established and, as people in rural communities are more closely inbred than those in dense urban communities, a greater prevalence of allergic states might be expected in rural areas.

Agglutinative Reaction for Hemophilus Pertussis and Immunity—Miller and his associates observed the persistence of agglutinins at a relatively constant level for six years after the administration of Hemophilus pertussis vaccine. The relationship between clinical immunity and the agglutinin titration of children given H pertussis vaccines was studied over a period of four years. Periodic tests were made in a group of 4 children. Seventy-nine indoor exposures twenty to 60

were familial, occurred. Ten cases of pertussis (6 from familial exposures) resulted. Among the 69 persons who escaped, the last agglutinative titer prior to exposure varied from 0 to 1:2,560. Forty-six had titers of 1:320 or higher. Among the 10 persons who were attacked with pertussis the preexposure titers varied from 0 to 1:160. These observations suggest that, whereas immunity may exist in the absence of demonstrable agglutinins, susceptibility does not occur in the presence of agglutinins in high titer.

Intravenous Human Plasma and Serum Therapy—Hill and Muirhead have described and advocated the use of concentrated plasma and serum. The small package and the increased speed and simplicity of use of dried plasma packaged for administration in concentrated form have been held to be of particular significance for military use. The authors present a study of reactions based on extensive observations on the preparation and administration of concentrated plasma in order to clear up misconceptions concerning the safety of this type of therapy and to establish confidence in its use. The observations deal with plasma prepared as previously outlined by the authors. The salient features of the method are: (1) pyrogen free technique for preparation of all apparatus, tubing and solutions, (2) sterile technique throughout checked by bacteriologic control studies, (3) pooling of blood of all different types just prior to separation of plasma, (4) bulk desiccation of plasma from the frozen state by the adreic process and (5) sterile transference of dry plasma to a small final container. Reactions are classified according to causative factors, namely factors inherent in plasma or serum factors introduced during the preparation factors associated with faulty administration, including contraindications and peculiarities or idiosyncrasies of the recipient.

The authors stress that properly prepared concentrated plasma is safer than whole blood transfusions. Although plasma prepared by pooling after separation of erythrocytes carries little risk, greater safety can be obtained by pooling of blood of all different types prior to separation. The table listing the febrile and urticarial reactions in the course of 1,160 injections in 520 cases shows a total of 24, or slightly over 2 per cent.

Aortic Embolectomy—Murray believes that complete obstruction of the bifurcation of the aorta from acute embolism is amenable to operative intervention. The technical procedure of removing such an embolus is not difficult. If undertaken within twelve to twenty hours after the accident and successfully completed, the results are exceedingly gratifying and the prognosis is changed to one of optimism, provided the preexisting cardiovascular disease has not in itself jeopardized the chances of the patient. The author reports five successful aortic embolectomies. There were no technical difficulties and no accidents or disasters. Several methods of approach have been studied and tried, but the one used in these 5 cases, which has been entirely satisfactory, has been through an extraperitoneal abdominal approach. The appearance of shrunken extremities is changed from the pallor and cyanosis of impending gangrene to that of a normal rosy pink. The patient is returned to the ward, when continuous intravenous heparin is given in sufficient quantity to keep the blood clotting time at about fifteen minutes for the following three days. In spite of the fact that most of these patients eventually die of embolism the patient can be completely relieved of symptoms and returned to the original state of health following the surgical treatment of the immediate episode.

Autotransfusion in Surgery of Serous Cavities—Griswold and Ortner think that all too often several pints of blood are thrown away from the body cavity of patients bleeding to death. It is their belief that this blood represents the most readily available, abundant, rapid and safe replacement therapy for these urgent cases. Large quantities of blood are often immediately accessible, the blood is compatible and needs no crossmatching and the danger of transmission of disease, such as syphilis or malaria, is absent as is the possibility of an allergic response. The authors give a brief history of autotransfusion in surgery of the serous cavities and analyze their own observations in one hundred consecutive autotransfusions. In twenty-two hemorrhage was due to ruptured ectopic gestation, and in the remaining seventy-eight penetrating and non-penetrating trauma to the thorax and abdomen was the etiologic agent. There were thirty deaths in this group or a mortality of 30 per cent. One fatal reaction occurred in the 100 cases. In this case there was a break in the technique of filtering the blood. In 2 other instances there were reactions from which the patient recovered giving a combined percentage of 3.0 for reactions. One patient had no reaction from the autogenous blood but had severe reactions on two occasions from blood obtained from the bank. Autotransfusion is a valuable adjunct in the treatment of internal hemorrhage. A simple suction apparatus is described which is more efficient in the collection of blood than mopping it from the body cavities. The technique particularly as regards filtration, must be rigid. Bile mixed with blood as the result of injury of the liver or biliary tree and bacterial contamination from hollow viscus perforation add danger to the procedure. This danger is not so great as might be thought and the need of blood is frequently far greater than the danger involved. Old blood because of hemolytic changes should not be used. Alkalinization of the urine may prevent reactions caused by partial hemolysis of the blood.

Globin Zinc Insulin—Lawrence advances arguments why globin zinc insulin should not be introduced for sale at the present time. Its action is weak and, like protamine zinc insulin, it will have to be supplemented by soluble insulin in many cases. Clinicians do not know whether globin zinc insulin contains an excess of globin or what the result is of mixing globin zinc insulin with soluble insulin. The fact that protamine zinc insulin is cloudy and soluble insulin clear is a great safeguard against mistakes between delayed action and quick acting insulins, but the new globin zinc insulin is a water clear solution, which is a serious disadvantage. Mistakes between insulins are all too common at present, and the author fears they will be far more so if another depot insulin appears on the market, especially if indistinguishable from soluble except for its label.

Faucial and Labial Diphtheria—Anderson describes a case of faucial and labial diphtheria in which the formation of labial membrane followed a slight injury to the lip. It is suggested that slight trauma to tissue may readily facilitate the introduction of Klebs-Löffler bacilli.

Jejunal Diverticulum J M Oviedo Bustos and J L de Grucci—p 273

Coccidiosis—According to Oviedo Bustos, *Isospora hominis* and *Isospora bigemina* are the two genera of coccidia which are parasitic for human subjects. *Isospora bigemina* was encountered in the 2 cases described by him. While the majority of cases reported in the literature originated in the eastern Mediterranean and in Japan, China and India, cases also have been reported from several parts of Argentina. Excreta of animals are presumably the cause. The symptomatology of coccidiosis, which is chiefly of the gastrohepatic and rectocolonic type, is accompanied by allergic phenomena. There may be dyspepsia and hepatic colics, constipation or diarrhea, flatulence, rectal tenesmus, anal pruritus and spasticity of the colon. The allergic phenomena are a generalized pruritus, erythema, urticaria, edema of the eyelids, rhinitis, asthmatic bronchitis and eosinophilia. The treatment is antiparasitic. Emetine, acetar-

son, chinofon and gentian violet are recommended. According to the experiences of Becker, vitamin B₁ and B₂ should be added. The author's observations indicate that *Isospora bigemina* is difficult to eradicate.

Relapse in Gonorrhea Treated with Sulfathiazole—Lemeweber reports observations on 38 women with gonorrhea. The infection was not complicated in 29 cases, while in 7 there was involvement of Bartholin's glands, in 1 adnexitis and in 1 vulvovaginitis. All women were treated with sulfathiazole. On each of two successive days they were given 2 tablets five times. Smears were taken on the first, fourth and seventh days after treatment, and when these were negative a provocative test was done on the eighth day. If at this time the smears were negative the patients were discharged, if not, another two day sulfathiazole treatment was given. This was necessary in two of the complicated cases. The second course of sulfathiazole was successful. Follow-up tests were made over a period of many weeks. The average control period for the 38 cases was seventy-six days, the longest was one hundred and forty three days. The follow-up examinations revealed 100 per cent freedom from relapse. Thus it can be said that two days of intensive treatment with sulfathiazole effects cure of gonorrhea and that there need be no fear of relapse. Sulfathiazole treatment not only shortens the clinical treatment of gonorrhea but is also highly reliable.

*Peroral Vitamin K Therapy S Thaddea and G Frost—p 186
Present Status of Pertussis Therapy O Chiari—p 189
A Diagnostic in Otalgia S Gitscher—p 190

Diagnosis and Treatment of Eclampsia—Headache, dizziness, "flitting flies," swimming of objects before the eyes and pains in the gastric region are prodromal symptoms of eclampsia. Treatment in this early stage consists of rest in bed and restriction of sodium chloride and fluid (5 Gm of sodium chloride and 500 cc of water per day). From two to four suppositories of theophylline ethylenediamine per day should be introduced for their diuretic effect. Intravenous injection of from 100 to 150 cc of dextrose solution as a substitute for venesection is recommended, to be given two to three times within twenty-four hours. As to surgical intervention, conservatism is to be practiced. Good results were obtained with Engelmann's therapy, combining Stroganoff's treatment with venesection, by substituting 500 cc of Ringer's solution (isotonic solution of three chlorides) for 400 cc of letted blood. Lately eclampsia has been considered as the result of excessive production of estrogens, and combined injections of progesterone and vitamin C are recommended.

Peroral Vitamin K Therapy—Animal experiments and clinical experience demonstrated that peroral administration of high doses of vitamin K in the form of "Karan" tablets (2-methyl-naphthohydroquinone-[1,4]-di-butylate) are effective in disturbances due to lack of prothrombin. From one to 1.0 002 Gm tablets are sufficient to normalize the prothrombin level of adults with the tendency to bleed. A higher dose will be necessary in cases with disturbances of liver function. The therapy failed in hepatocellular icterus particularly in biliary cirrhosis. No untoward reactions were observed. There is less danger of overdosage than of underdosage. Vitamin K therapy is indicated as a preoperative or postoperative therapy to reduce the tendency to bleed in obstructive icterus, in the rare cases of biliary fistula, in cases of inoperable tumor of the biliary ducts, as a medicinal treatment of hemorrhagic states in disturbances of fat absorption (gastrocolic fistula sprue) and in the newborn with a physiologic lack of prothrombin.

Book Notices

A Handbook of Psychiatry By P. M. Hechtstein M.D. LL.B. in Charge of Psychiatry and Legal Medicine for the District Attorney County of New York and S. M. Small B.S. M.D. Psychiatrist and Assistant Medical Director National Hospital for Speech Disorders New York Cloth Price \$3.50 Pp. 330 New York W. W. Norton & Company Inc. 1943

This book is a valuable contribution because of the simplicity of its language and the clearness of its expression. It defines various terms in psychiatry with ease. It does not discuss any controversial issues but contains well proved facts. The book contains sixteen chapters on normal personality functioning, abnormal behavior, the mental examination, psychometric tests, feeble-mindedness, psychopathic personality, psychoneuroses, war psychoneuroses, psychosomatic illnesses, mood disorders, schizophrenia, paranoia and paranoid reactions, delirium and allied conditions, organic brain disorders, general principles of psychiatric therapy and therapeutic aids. The contents are not detailed but they cover briefly the essentials of psychiatry. The authors have used case material from their court records in giving examples of the various diseases in psychiatry. There is a bibliography after each chapter. This book is recommended chiefly for the general practitioner, the nurse and the social worker. There is a definite need for such a book presenting such easy and fact finding reading.

Hypnotism By G. H. Estabrooks Cloth Price \$2.00 Pp. 249 New York E. P. Dutton & Co. Inc. 1943

There is certainly a need for a popular or semipopular book on hypnosis, but this current jumble of truth and speculation cannot be considered the answer from the physician's point of view. Although the author in his preface claims that the facts and rules of hypnosis are as scientific as those of chemistry, this is pure balderdash and the book cannot bear out his contention. Books on hypnosis have run the gamut from charlatan 5 cent books on how to hypnotize and conquer the world to the excellent scientific products of Bramwell and Clark Hull. Although Estabrooks is a professor of psychology at Calgate University, the material in this book does not bolster his position as an authority on the subject. He makes bald statements which are not currently believed such as 'cases of kleptomania or compulsive stealing fit into the picture of posthypnotic suggestion'. He cites examples from his own experience which have no reported counterparts elsewhere in the literature and hence are not verifiable. He speculates in extenso about Hitler's hypnotic ability and makes some bizarre suggestions about how hypnosis could be utilized in warfare, which if carried out, to this reviewer's mind, would probably be as dangerous as valuable. For instance, the author believes that a man could be given false information under hypnosis and give it out as sincere when captured by the enemy, thus misleading the latter a doubtful project. The chapters which are largely descriptive, such as those on the induction of hypnosis, the more common phenomena of hypnosis, also hypnotic suggestion, are interesting and not bad. However, his psychosomatic examples of the use of hypnosis in the removal of thoracic pain in tuberculosis or in rheumatic cases cited from another author, are misleading. The style is light and easy to read, at times it borders almost on the point of boudoir intimacy, but the physician might well be advised to reserve his reading on the subject until a more scientific book of the same general nature appears.

Surgical Care: A Handbook of Pre and Post Operative Treatment By R. W. Raven F.R.C.S. Major R. A. M. C. Assistant Surgeon Royal Cancer Hospital London Cloth Price \$3 Pp. 271 with 80 illustrations Baltimore William Wood & Company 1942

'Surgical Care' is a rather ambitious title for this small volume. The book attempts to cover all the specialties of surgery and hardly does justice to many of them. The subtitle is not adhered to very rigidly, as there is relatively too much of the basic sciences. There is much good material of practical value in this book though many surgeons will not agree with some of the methods advocated. Much of this bears elaboration, and some of it is passed over too briefly. The context seems, in general, too elementary for the surgical house staff and in places too advanced for the nursing staff.

Introduction to Organic and Biological Chemistry By L. Earle Arnow, Ph.D. M.D. Director of Biochemical Research Medical Research Division Sharp & Dohme Inc. Clenolden Pa. and Henry C. Reltz Ph.D. Assistant Chemist in the Western Regional Research Laboratory United States Department of Agriculture Albany California Cloth Price \$4.25 Pp. 736 with 91 illustrations St. Louis C. V. Mosby Company 1943

One of few combination textbooks on organic and biologic chemistry, this is designed by the authors for use in premedical, preclinical, home economics, agricultural, dietetics and physical education curriculums. It may be well adapted for all except premedical courses, being too brief for adequate preparation in either the organic or the biochemical phases. Of the three parts, part I is devoted to a review of chemical fundamentals. These include the elements, atomic theory, structure of the atom, valence, ionization (from the Arrhenius theory), acids, bases and salts (according to classic theories) and solutions. Unfortunately, no mention is made of newer concepts of ionization or of acids and bases. Part II, of approximately five hundred pages, is devoted to organic chemistry, covering adequately all the topics usually found in an elementary organic textbook, with illustrations and special emphasis on compounds of biologic and medicinal interest. Amino acids are presented as uncharged ions, making it difficult for the reader to appreciate fully the amphoteric properties of proteins. Part III, of about two hundred pages, covers the biochemical topics of enzymes, respiration, carbohydrate, fat, protein and mineral metabolism, hormones, vitamins and nutritional requirements. The division of the book into three distinct sections makes the inclusion of organic and biologic chemistry in one volume of less unique value than if an integrated treatment of the two fields had been attempted. At the end of each chapter, study questions and references to current literature, textbooks and reviews are given. In an appendix are extensive tables of the composition and caloric value of foods. At least one error requiring attention in future editions should be pointed out. The reference (p. 90) to methyl chloride in household refrigeration as "nontoxic to man, a valuable property in case of a leak in the refrigeration system," is a misstatement, for the compound is definitely toxic.

The Examination of Waters and Water Supplies (Thresh, Beale & Suckling) By Ernest Victor Suckling M.B. B.S. M.R.C.S. Consulting Bacteriologist and Analyst to Various Water Authorities Fifth edition Fabrikoid Price \$12 Pp. 849 with 63 illustrations Philadelphia Blakiston Company 1943

The fourth edition of this standard textbook appeared in 1933 under the authorship of Thresh, Beale and Suckling. With the death of Dr. Thresh and the retirement of Dr. Beale, Dr. Suckling, a distinguished English bacteriologist, has assumed responsibility for the volume, long known to British and American workers in the water supply field. The fifth edition follows closely in form and content the subject matter and treatment presented in the fourth edition with only minor extensions in text, generally adequately designed to include new or to expand old data. For example, almost four pages have been added on the detection and estimation of fluorine, while the chapter on intestinal organisms used as indexes of pollution has been adjusted and expanded to give recognition to developments in British and American laboratory and field practice. In similar fashion the chapter on standards and standardization has been elaborated with more discussion of American practice. Unfortunately, the text was prepared before the U. S. Treasury Department standards were revised and released in 1943 since these modify materially the data and discussions now in the text. The volume pays somewhat of a penalty for the effort to supply so vast a coverage in the water supply field since the chapters have a scope beyond that indicated in the title. Part VIII covering the purification and treatment of water represents, for example, some one hundred and thirty-five pages or over a fifth of the total text. Although excellent in treatment, it suffers through the necessity for sharp compacting in space. Perhaps it deserves a separate volume. The volume unlike most American textbooks carries a great deal more backing up and historical material. Such a practice has real merit although again it gives some impression of diffuseness in those sections largely devoted to the exposition of the title. The book is a welcome revision of an old standby and should be available to all workers in this field.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON JOURNAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

GAUZE MASKS TO PREVENT CONTAGION

To the Editor—I am attempting to obtain the general consensus regarding the value of wearing masks in contagion. I should appreciate an opinion for or against the use of the standard six thickness gauze mask by attending physicians and the nursing staff. I should like this information particularly with reference to epidemic meningitis, tuberculosis, diphtheria and virus pneumonia.

C. G. Peterson, M.D., San Bernardino, Calif.

ANSWER—The most that can be expected from masks is the enmeshing of the coarser droplets of saliva or nasopharyngeal secretions while breathing, coughing, talking and sneezing. They are not a barrier to dried minute particles of infectious material either bacterial or viral in nature which float about in the air, and they obviously do not keep infectious material from contact with the conjunctivas.

In a recent publication (*Science* 97:229 [March 12] 1943) Francis states that "the ordinary gauze mask is not only not beneficial but actually harmful." He recommends a new type of mask containing flannel filters. When properly fitted they filter infectious particles from the air and become even more efficient after laundering.

Efficient masks would no doubt aid in preventing the spread of the four diseases listed, but perhaps other measures at present under investigation such as ultraviolet irradiation of the air, the use of aerosol sprays or chemoprophylaxis may eventually prove to be even more effective.

[This query was submitted to a prominent internist, whose reply appears. Opinion on this subject, however, is greatly divided and some internists and pediatricians recommend and enforce the use of gauze masks for persons taking care of patients with communicable diseases. The question does not appear to have been settled.—Ed.]

OSTEOCHONDRITIS DISSECANS OF KNEE

To the Editor—A patient has osteochondritis dissecans with secondary hypertrophic osteoarthritis which resulted from an injury to her left knee. She suffers considerable pain and is unable to use the knee. What treatment would you advise for this condition and would diathermy be of any benefit?

J. L. Snively, M.D., Sterling, Ill.

ANSWER—Osteochondritis dissecans of the knee may occur at any age from puberty on, but osteoarthritis is usually seen in people of early middle age on.

If in the case mentioned there is a loose body, it should be removed and the area of origin—usually the internal condyle of the femur—smoothed down. This will relieve the patient of the discomfort—usually catching or locking of the joint—and the associated irritation of the joint lining caused by a wandering osteocartilaginous body.

The osteoarthritis is a separate condition and is best treated by restriction of excessive activities and heat locally to the joint by hot packs, baking or diathermy.

PLASMOCHIN FOR MALARIA

To the Editor—In the authorized manual of therapy issued to army medical officers the following statement appears: "Its [plasmochin's] most striking action is on the gametocytes of *P. falciparum*, which it devitalizes and renders noninfectious. When the latter drug is administered as described above, the relapse rate appears to be substantially lowered." It is my understanding that gametocytes represent the end stage of the plasmodium in the human host and do not differentiate further or cause symptoms unless first undergoing sporogony in the *Anopheles* mosquito. If this concept is true, can a relapse occur in man from the presence of gametocytes alone and what would be the explanation thereof?

Captain, M. C., A. U. S.

ANSWER—Although there are some reports which indicate that plasmochin may reduce the relapse rate of malaria, those most familiar with the use of this drug doubt if it has the effect on relapses indicated in the authorized directive. It is probable that the directive will be altered soon and that the use of plasmochin will no longer be recommended.

The gametocytes originate from the asexual parasites and, although the sexual forms are noninfectious for man and produce no clinical symptoms, they are undoubtedly always accompanied by a stage of asexual parasite which can initiate the relapse.

PARESTHESIAS AND POSSIBLE EFFECTS OF PROLONGED ETHER ADMINISTRATION ON ANESTHETIST

To the Editor—Are there any instances of ill effects to anesthetists who are regularly exposed to ether fumes over long periods of time? I have been giving anesthetics for some twenty years. Much of the time my breath carries the odor of ether hours after exposure. For the past five years or more I have experienced paresthesia in my feet. This has extended well up to my knees, and now my hands have a similar sensation. It seems to me that it is progressing and becoming more like a peripheral neuritis with some shooting pains. Is it reasonable to think that ether fumes could be the source of irritation? Outside of this annoyance, I feel very well for a 62 year old.

M. D., Kansas

ANSWER—There are no proved cases on record of ill effects to anesthetists from inhalation of ether vapor as a result of administering ether to patients by standard methods. It is not clear why an anesthetist's breath would carry the odor of ether for hours after exposure to the anesthetic agent unless through some individual technique of administration, the anesthetist inhaled undue amounts of ether from time to time. It is improbable that inhalation of ether fumes would cause paresthesia of the feet. Other causes for such disturbances should be sought. Not infrequently elderly persons complain of severe paresthesia, particularly burning, in the feet for which no good reason can be found. It is believed that in many of these cases the cause is senile degenerative changes in the sensory tracts of the central nervous system.

SOLVENT FOR REMOVAL OF ADHESIVE TAPE

To the Editor—I have observed industrial medical departments using benzene for the removal of adhesive tape. It is obvious that this is a bad practice as it exposes the nurse who employs this technique to the inhalation of toxic concentrations of benzene vapors. A death from chronic benzene poisoning occurring in a switchboard operator who over a period of years had used benzene on a rag to clean her switchboard has previously come to my attention. I should appreciate an opinion from you as to the dangers of this procedure and as to the most satisfactory safe solvent which could be used as a substitute.

L. M. Petrie, M.D., Atlanta, Ga.

ANSWER—Chronic benzene poisoning has been produced in workers exposed repeatedly to low concentrations of this substance and for this reason it is not believed that benzene is a satisfactory material for the removal of adhesive tape in dispensaries and hospitals. It is, of course, necessary to use a material which is a good solvent for the adhesive in the adhesive tape and at the same time a substance which is relatively nontoxic and which possesses a somewhat high flash point in order to obviate the possibility of readily taking fire.

A solvent which answers these requirements is Stoddard solvent or high flash naphtha. Stoddard solvent is a straight run petroleum naphtha and possesses a flash point above 100°F. Stoddard solvent is used to a great extent in the dry cleaning industry as a substitute for carbon tetrachloride because of its nontoxic properties and its high flash point.

ESTROGENS FOR BOTH AMENORRHEA AND MENORRHAGIA

To the Editor—On page 716 of the July 3 issue of *The Journal* it is recommended that a patient with excessive vaginal bleeding be given oral estrogenic therapy. Some gynecologists have suggested using estrogens to produce bleeding in cases of amenorrhea or oligomenorrhea when the anatomy seemed normal and no pathologic condition was discernible. Disregarding the advisability of the latter procedure, at least it ought to be admitted that the two therapeutic uses of the drug are incompatible the one with the other because the same agent, estrogen, has been used to promote bleeding in one case and to stop it in the other. It would at first hand seem that this is unreasonable, that estrogen, if valuable in one case, would be contraindicated in the other. What is the basis for the use of estrogen in a case of bleeding as recommended in the answer cited? William J. O'Neal, M.D., Detroit.

ANSWER—It is well known that thyroid medication at times checks profuse uterine bleeding and at other times induces menstruation in cases of amenorrhea. Likewise, estrogens can be used to overcome both amenorrhea and menorrhagia. The effect produced depends on the level of estrogen in the blood. At certain levels bleeding is induced, and at other levels bleeding is checked. There have been clinical reports proving that oral estrogens may successfully be used for the two diametrically opposite clinical manifestations. Palmer (*Am J Obst Gynec* 41:1018 [June] 1941) prescribed diethylstilbestrol for 31 women aged 12 to 55 who suffered from abnormal uterine bleeding and observed favorable results. Cuyler, Hamblen and Davis (*J Clin Endocrinol* 2:438 [July] 1942), checked prolonged or excessive uterine bleeding in 11 of 15 women by giving them diethylstilbestrol orally. The average time to producing hemostasis was 4.4 days and the daily dose varied from 2 to 6 mg. Karryak (*Year Book of Obstetrics and Gynecology*, by J. P. Greenhill, 1942 p. 535) claims that 87 per cent of women with severe functional bleeding treated with diethylstilbestrol regular menses will return.

TROPICAL MYCOSES

COMDR LEE MCCARTHY, MC-V(S), USNR

Tropical diseases, and particularly those involving the skin which are due to the higher fungi, are going to occupy the attention of the medical profession both at home and abroad, in the civilian population as well as in the military or naval services more and more, the longer the war lasts. Rare mycotic infections which are unusual in this country will gradually be recognized as commonplace while exaggerated clinical manifestations of the commoner fungous diseases of the skin, already well known to us but aggravated by their origin in the tropics, are now being seen in large numbers in men returning from the South Pacific areas.

All physicians should be aware of the possibility of the occurrence of these conditions here at home and be able to recognize them and stamp them out before they can become endemic.

It has been definitely proved that many of the more serious systemic fungous diseases begin with nodules or ulcers on the skin. Also that if the skin lesions are recognized early and the proper diagnosis is made, treatment will in most instances prevent a general dissemination of the disease, which very frequently results in death.

Although there still exists a certain amount of confusion with regard to the classification of the parasites of the ascomycetes and the hyphomycetes group which cause these diseases, their morphology, cultural characteristics and occurrence in the lesions are so well understood that early diagnosis and the institution of early treatment should be within the scope of all physicians both at home and in the services.

Tropical mycoses are due mainly to the so-called higher fungi and may be divided into two classes.

First, the Ascomycetes (fungi that produce an ascus [sac] to hold spores) (a) *pie*dra (trichosporosis), (b) rhinosporidiosis (c) lymphangitis epizootica, (d) histoplasmosis.

Second, the Hyphomycetes (fungi imperfecti) (a) pityriasis versicolor (tinea versicolor), (b) erythrasma, (c) trichophyton infections of the glabrous skin, (d) epidermophyton infections of the glabrous skin, (e) epidermomycoses originating only in the tropics (1).

This paper is a symposium on Tropical Diseases of the Skin is published under the auspices of the Section on Dermatology and Syphilology.

This portion of the symposium is presented as a review of the latest monographs on fungous diseases arising in the tropics with certain conclusions reached after a year's experience with men returning from the tropics.

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writer and are not to be considered as reflecting the policies of the Navy Department.

endodermophytoses, (2) cladosporian dermatoses, (3) aleurosporian dermatoses, (4) two dermatoses probably due to trichophytons.

THE ASCOMYCETES

Piedra (trichosporosis) — This is a fungous disease involving the exterior of the shaft of the hair, particularly of the scalp and beard. It consists in the formation of tiny dark or light brown stony, hard nodules, scarcely perceptible to the eye, but which can be definitely felt when the hair is drawn between the fingers (McCarthy¹). It occurs in Europe, Asia and Japan as well as in South America (Colombia) and is thought to arise in persons who wash their hair and beard in stagnant river water and then apply a thick oily or mucilaginous substance as a hair dressing. After the hairs are soaked overnight in 20 per cent potassium hydroxide solution, the nodes are seen to be made up of a large number of closely packed contoured spores.

The mycologic aspect of this disorder has been studied in detail by Bodin,² Vuillemin,³ Schaechter,⁴ Lombardo,⁵ Lampe⁶ and others. It is generally agreed that the parasite is a fungus and should be classified as a member of the ascomycetes group. *Trichosporum giganteum*, *Trichosporum beigelii*, *Trichosporum ovoides* and *Trichosporum ovale* have been commonly reported from the different regions in which the disease occurs. Chalmers⁷ has reported a form of *pie*dra which he calls trichonocardiasis, which is due to a species of *Nocardia* (actinomycetes). All these parasites grow slowly on Sabouraud's medium but better on carrots.

Trichosporosis must not be mistaken for trichorrhexis nodosa, a nonparasitic involvement of the hair shaft in which the hair is fractured transversely, resulting in a splitting of the ends into brushlike bundles of fibers. It should not be confused with monilethrix, which is nonparasitic and is congenital and hereditary and often the result of congenital syphilis. Trichosporosis differs from leptothrix by its regional distribution, color and type of parasites which are cocci or bacteria. Nits project off at an angle from the shaft, while in trichosporosis the shaft is more or less completely surrounded. In treatment the hair should be cleansed with benzine or ether or acetone. A 1 to 1,000 solution of mercuric bichloride or a 3 per cent sulfur and a 3 per cent salicylic acid ointment can be effectively applied. Shaving

of the part, with application of the bichloride solution, is a rapid, effective method when it is possible to use it.

Rhinosporidiosis—This is a fungous disease chiefly of the mucous membranes of the nose with the production of polyps. Recent reports show that the eais lacrimal sac, uvula and the mucosa of the penis may be involved. The causative organism *Rhinosporidium secheri* was at first thought to be a coccidial parasite, which it closely resembles, but it is now known to be a true fungus and is found in large numbers within the soft, raspberry-like growths it causes. It has been reported from Cochin China, South America and the United States.

The mode of transmission of the disease is not known, but a closely related disease due to *Rhizopus equi* has been reported in horses in these regions. Treatment consists in removal of the polyps with a wire snare from the nose and destruction with electrocoagulation of the tumors from other regions, combined with the use of antimony and potassium tartrate.

Lymphangitis Epizootica—According to Stitt⁸ human beings working with horses suffering with this

Achromatic punctate type of tinea versicolor acquired in the tropics

fungous disease may develop nodules and ulcerations of the skin in areas rich in lymphatics. Cases have been reported from Asia (India, China and Japan), western Europe and northern Africa. Man appears to be only an accidental host, and no visceral or systemic involvement has been reported. The organism is a cryptococcus of the farcinosus or pschrophylicus type and has been easily cultivated at 22 C and successfully inoculated in guinea pigs, rats and white mice by Nino.⁹ Treatment consists in early incision and curettage of all the lesions combined with the use of arsenicals intravenously.

Histoplasmosis—Although the causative agent, *Histoplasma capsulatum*, usually produces a serious systemic disease with involvement of the deeper organs, the infection may begin on the skin as nodules and ulcers, particularly on the face. An early diagnosis, with excision and curettage of the lesions, combined with the use of fuadin, asphenamine or antimony and potassium tartrate, may prevent systemic involvement, which often has a fatal termination. The disease, when well

developed, resembles the clinical picture of kala-azar. It has been reported from South and Central America (Panama), North Africa and Asia, as well as in the United States. In cultures and in smear preparations the parasite resembles a cryptococcus, and Benham has suggested the name *Cryptococcus hominis* for the organism.

THE HYPHOMYCETES

The Hyphomycetes are less perfect fungi than the Ascomycetes in that they do not produce a sac at the end of a hypha to hold their spores but exist as a mass of ramifying, threadlike filaments (hyphae), which is called the mycelium. Reproduction and growth take place by the lateral, angular or terminal addition of new hyphae or by the division of a single hypha.

Pityriasis Versicolor—This is widespread and therefore the best known of the epidermomycoses. It occurs in temperate climates about as often as in the tropics, but in hot countries the eruption varies somewhat in color and in distribution. Instead of the typical cafe-au-lait colored scaly, greasy macules, one may find three atypical clinical expressions of the disease: (1) the red, or erythematous, form, (2) the circinate erythematous and squamous form and (3) the achromatic form. It is believed that these types are due to excessive sun, heat and humidity and really represent different degrees of the brown type, for the red and achromatic lesions become the usual brown type once the patient leaves the tropics. Again, the brown type may be found on the covered parts of the body, along with the red or achromatic types on the exposed portions. The same parasite, *Microsporum furfur*, can be obtained in all variants.

The achromia is an actual depigmentation rather than an impression gained by contrasting normal and abnormal skin areas. It is thought to be due to three factors: (1) the screening action of the scales, (2) the decoloring action of the sun and (3) the disturbance in pigment function of the skin due to the toxins produced by such large numbers of fungi.

Clinical variations of all the different types may be seen frequently in the tropics. The eruption may be limited to only the face or the scalp or to the backs of the hands. The lesions may be milium and punctate and remain so throughout the course of the disease with no tendency to coalesce until the entire trunk and the proximal halves of the extremities are completely covered. Circination, with the formation of small papules, has been reported.

The treatment of this mycosis consists in thorough removal of the scales by scrubbing with tincture of green soap followed by the application of 1 per cent solution of iodine crystals in alcohol or a 4 per cent solution of salicylic acid in alcohol or a 1 per cent chrysarobin ointment plus disinfection of the undergarments (underwear and nightclothes). Weeks of treatment are necessary, as the disease shows a definite tendency to relapse.

Erythrasma—This condition, which is due to *Microsporum minutissimum*, differs little in its tropical form from the type seen in temperate climes. The eruption is more inclined to involve several areas at one time; that is, the axillary regions, the mammillary and rectal folds, the region of the umbilicus and the web spaces of the toes as well as the inguinal folds and inner surfaces of the thighs. As the result of chronicity,

⁸ Stitt, E. R. *Diagnosis and Treatment of Tropical Diseases*, ed. 6, Philadelphia, Blakiston Company, 1942, vol. 3, p. 1158.
⁹ Nino, F. L., quoted by Stitt. *Diagnosis and Treatment of Tropical Diseases*, p. 1159.

the accompanying itching and scratching, the skin of the plaques may be thickened and lichenified and may be mistaken for neurodermatitis or the ordinary tinea cruris. The vesicles and pustules are not fungous in nature and are due to infection with cocci resulting from scratching.

The treatment of uncomplicated cases is the same as for any of the superficial mycoses. If eczematization and pustulation have taken place, these must be treated before the parasite is attacked. Disinfection of the clothing is important but is often neglected and accounts for many of the relapses.

Trichophyton Infections of the Glabrous Skin—These eruptions, seen in the tropics, are usually due to the frond type such as *Tinea alba*, which produces generalized eruptions of small, dry, scaly lesions, or to the small spored (microid) type, such as *Trichophyton asteroides*, which produces large solitary, deep, pustular lesions (kerion) or acute pustular eruptions on the fingers and dorsum of the hands. This parasite, or some of its variants, such as *Trichophyton granulosum*, may produce virulent forms of sycosis barbae. All these parasites are of animal origin, belonging to the horse, dog or cat. *Trichophyton rosaceum* and *Trichophyton violaceum* are especially prevalent in the Far East and cause a type of dry, scaly and to a less extent pustular form of sycosis barbae very difficult to cure. Occasionally any of these parasites may be isolated from the usual eruption of tinea cruris, which is thought to be due to the epidermophytons as a rule.

After a year's experience with men returning from the tropics with ringworm infection of the skin, I have come to the conclusion that the large majority of the cases consist of the usual run seen in the United States but in a more exaggerated form. Three types of ringworm predominate. The commonest type is acromycosis (McCarthy¹⁰) often described as epidermophytosis, of the feet and hands. The eruption is extensive, covering the dorsum and sides of the feet and hands as well as the soles, palms and lateral surfaces of the digits. It is practically always pustular in character with strong tendencies to develop secondary lymphangitis and regional glandular enlargement. The eruption is very resistant to treatment and shows tendencies to recur when the patient returns to active duty. The following parasites have been cultured from this type: *Trichophyton purpureum* and its two variants, *Trichophyton plurizoniforme* and *Trichophyton lanorosum*. *Epidermophyton inguinale*, *Trichophyton interdigitale* and occasionally *Trichophyton asteroides*.

As a complication to acromycosis I have noted that there was also a ringworm infection of the superficial pustular type on the lower two thirds of the legs in many instances. These lesions often become secondarily infected and result in multiple ulcers varying in size from that of a split pea to that of a hazel nut. Sulfonamide ointments have no effect on these ulcers. After weeks they heal with the use of wet compresses of 1 to 8,000 potassium permanganate solution and 25 per cent cod liver oil ointment. Although the interdigital parasite was found in a large number of these lesions no secondary invaders could be demonstrated. Compresses with gramicidin solution were of no benefit

and seemed to cause irritation in our cases. In many of the cases with superficial ulcers, healing did not take place, even after all signs of infection had disappeared, until the congestion of the skin was overcome. A piece of sponge rubber large enough to extend 1 inch in all directions beyond the margins of the ulcer was applied over the potassium permanganate compresses. The entire lower part of the leg, beginning over the dorsum of the foot, was then wrapped with an Ace bandage, which was left on for eight hours each day. At night the cod liver oil ointment was applied. The value of this combined method of treatment cannot be too strongly emphasized.

The second type, or tinea cruris (eczema marginatum) presented the same morphologic characteristics as we are accustomed to see at home, but the lesions were more extensive and more inflammatory as a general rule. The eruptions responded nicely to treatment but tended to relapse once the patient perspired or returned to duty. It was necessary to continue treatment for two months after all clinical signs of the disease had disappeared. *Trichophyton purpureum* and *Epidermophyton inguinale* were the only parasites cultured. Cultures were obtained in about one third of the cases of this type.

The third type was extensive tinea corporis, covering the trunk, front and back and the proximal third of the upper arms. The eruption consisted of complete or incomplete annular lesions separated by small areas of normal skin. They were only slightly inflammatory and were covered with very fine branlike scales but showed no vesicles or pustules. Itching was intense. The clinical picture did not suggest a tinea imbricata, and only *Trichophyton rubrum* or its two variants, *Trichophyton lanorosum* and *Trichophyton plurizoniforme*, were found in the scales in about one third of the cases. This type of eruption responded nicely to an ointment containing 3 per cent iodine and 3 per cent glycerin in petrolatum. A 5 per cent ammoniated mercury ointment or a 3 per cent chrysarobin ointment produced so much irritation that it was necessary to stop them entirely. Whitfield's ointment, unless used in full strength, was not effective and was too irritating when applied to extensive body surfaces.

Tropical Epidermomycoses—In the stricter sense of the word "tropical," this term has been used to describe a group of fungous diseases that are found only in the tropics and that involve the skin almost exclusively. They differ widely in their clinical manifestations, their etiologic agents and their geographic distribution. So far I have had no personal experiences with these rarer types of fungous diseases. Langeron¹¹ has divided them into four groups according to the type of parasite that causes them:

- 1 Endodermophytoses, which are produced by a group of endodermophytons (trichophytons) with faviforme cultures which attack only the skin and never the hair or deeper structures to form kerion or granulomatous lesions. Nor do they invade the blood stream. In this group are found tinea imbricata, chumbea and tinea intersecta.

- 2 The cladosporian dermatoses (hormodendron and cladosporium). Two types are recognized: (1) the achromatic type (parasitic achromia of Jeanselme) (2) the hyperchromic type (tinea nigra and keratomycosis nigricans palmaris).

¹¹ Langeron M. *Nouvelle pratique dermatologique*. Paris: Masson & Cie, 1936, vol. 2, p. 315.

3 The dermatoses caused by parasites that produce aleurospores (*tinca albigena*, *khi-hueri*) This type may produce mycetoma as well as involve the skin

4 Two dermatoses probably due to trichophyta but insufficiently studied (tropical ringworm of Sabouraud and *tinca nigrocircinata*)

Tinea Imbricata (Tokelau) — This is a very pruriginous tropical skin disease that is characterized by the appearance of concentric circles or rings formed of scales which are attached on their periphery and are free at the center. The circles may assume a definite rosette-like pattern designated as cocards. At times the scales may be layered like the shingles on a roof. The fungus advances peripherally, leaving a smooth surface within the circle. A similar process again develops in the original central spot and forms a circle of scales within the older, or more peripheral, circle. The process is repeated until several rings of scales are formed, each originating from the central focus, the way concentric ripples form on water from the fall of a pebble, according to Stitt.¹² The circles are from one-eighth to one-half inch apart and the eruption may spread to involve the entire body with the exception of the axillae, groin, palms and soles. The nails have practically never been invaded.

The disease is due to a special type of fungus called *Endodermophyton concentricum* because it proliferates only within the skin never penetrating deeper into the tissues and never attacking the hair. There is an entire absence of inflammation, which separates it from all other types of tropical ringworm. *Endodermophyton indicum* has also been cultured from the scales. This parasite produces a reddish culture, while *Endodermophyton concentricum* (*Endodermophyton tropicale*) produces a grayish white culture. Recent researches on *Epidermophyton purpureum* (*Trichophyton rubrum*) have shown that production of pigment is most variable on different batches of the same medium and is really only a secondary characteristic. Most authorities feel that the two parasites are identical. McCarthy¹³ was able to prove by inoculation of guinea pigs that *Trichophyton rubrum* was really an *endodermophyton*, as it never attacked the hair or the deeper structures. Two other species reported in this mycosis, *Endodermophyton tropicale* and *Endodermophyton mansonii*, are now recognized as being identical with *Endodermophyton concentricum*. Langeron¹⁴ believes that *Trichophyton concentricum* is the proper designation of the one and only fungus that causes this disease.

Although parasitic mycelia were first demonstrated in the scales in 1879 by Manson¹⁵ in China, the disease had been recognized clinically as early as 1686 in the Tokelau Islands. It is now widespread in all hot and humid parts of the islands of the South Pacific, the Malay Archipelago, southern China, southern India, Ceylon, Colombia, Brazil and Guatemala. No authentic case has been reported as originating in the United States. The disease is refractory to treatment. Manson¹⁵ recommended an iodine liniment containing 12.5 per cent iodine, as he found that the 7 per cent tincture was not strong enough to be effective. Two to 5 per

cent chrysarobin ointment has been used by many authors. Castellani¹⁶ prefers 60 to 120 grains (4 to 8 Gm) of resorcinol in 1 ounce (30 cc) of tincture of benzoin. These preparations will not be effective until the scales have been removed by thoroughly scrubbing the skin with hot water and tincture of green soap or sand soap. Sterilization of the clothing is most important, boiling or destroying them by burning is an absolute necessity.

Chumbeira — This is the name given to a fungous disease of the skin which is found in Brazil and which has often been confused with *tinea imbricata* or pinta. It was first reported by Fonseca¹⁷ in 1924, who isolated and cultured a parasite from the scales and called it *Trichophyton roquettei*.

The lesions consist of large, achromatic, annular or circinate, very pruriginous patches that are covered with a thick layer of scales. Even the scales have a translucent or whitish color. The scales are thickest on the edges of the patch and are easily detached. Practically any part of the body surface, with the exception of the hair and nails, may be involved.

This type differs from the usual ringworm of the glabrous skin by its constant and pronounced depigmentation, the absence of erythema and vesicles, and the fact that the scales are much thicker on the borders than in the center of the lesions.

Tinea Intersecta — This type of fungous disease is characterized by the appearance on the skin of papules which dry out and split across the top. It is widespread through Ceylon and southern India and southern China. Mycelial threads are easily demonstrated in potassium preparations of the scales, which produce a reddish faviforme culture on Sabouraud's medium. The parasite is called *Endodermophyton castellani* and has been transmitted from man to man but not to laboratory animals.

The disease begins as tiny, slightly elevated, deeply pigmented papules separated from one another by a narrow zone of normal skin. They enlarge very slowly, become very hard, dry out and crack transversely. They may remain solitary or coalesce to form irregularly sized and shaped plaques. The splits in the papules deepen until the lower layers of skin are involved. In this fashion large, thick, brownish scales are desquamated, leaving behind round or oval areas of whitish, depigmented skin similar to the desquamated areas seen in *tinea imbricata*. Rosette-like patterns never develop in this disease. Itching is intense over the involved areas, which may include especially the arms, legs, chest and back. No visceral or systemic involvement has been reported.

The disease is evidently benign, for it is easily cured with tincture of iodine, full or half strength, a 5 per cent ammoniated mercury ointment or a 3 per cent chrysarobin ointment.

Cladosporian Dermatophytes (parasitic achromia or Jeanselme, *tinea flava*, hodi-potsy) — Although Castellani¹⁸ classified this eruption as an atypical type of pityriasis versicolor involving only the face and neck that was due to one of the *Malassezia*, which he called

Malassezia tropica, the work of Jeanselme,¹⁹ and more recently that of Fontoynt and Carougeau²⁰ have shown that this is a disease entity per se and is caused by a conidiospored hyphomycete of the genus *Hormodendron* (Cladosporiae). According to Langeron,²¹ this parasite should be called *Hormodendron fontoynti*. Parasitic achromia is widely distributed and extremely common in all tropical countries. In Asia it has been found in the Indies, Ceylon, Malay Peninsula and Indo-China also in Africa, Madagascar and Nigeria. So far in South America it has been reported only from Brazil. This disease penetrates deeply into continents rather than remaining an insular coastwise disease, as is *tinea imbricata*.

The disease is characterized by the production, only on the glabrous skin of the face and neck, of scaly whitish plaques. The plaques, at first separated by areas of normally pigmented, healthy skin, gradually enlarge until large areas are involved. The eruption stops abruptly when the bearded or hairy portions of the face are reached. The lesions do not itch, and no papules or vesicles have ever been reported. The edges of the patches are not elevated, and no signs of inflammation are seen. The disease is very contagious, runs in families, and has periods of seasonal exacerbations. It almost dies out in the wintertime, only to flare up in the hot moist summertime.

The parasite appears as elongated straight or short curved mycelia, with single spores or spores in chains, when seen in potassium preparations. The culture begins as a white downy colony, which later becomes a deep greenish black.

The disease should not be confused with *tinea versicolor*, vitiligo, syphilitic leukoderma, macular leprosy or seborrheic dermatitis.

After removal of the scales by scrubbing with sand soap and water, the disease responds nicely to the usual antiparasitics mentioned in the previous paragraphs.

Tinea Nigra (sometimes called *pityriasis nigra*)—This is the second member of the group of mycotic skin diseases due to a member of the family of the Cladosporia. It has been reported in southern China, Ceylon, Burma and the southern part of India and is fairly widespread and commonly seen in all these regions. The eruption is characterized by the gradual development of dull black, slightly elevated and slightly scaly, nonpruriginous, various sized spots on any part of the body except the face.

Potassium preparations of the scales show pigmented elongated mycelial threads and oval or round spores. On the usual mediums a blackish faviforme culture, which grows slowly into the depth of the medium, is produced in about six weeks. The parasite is called *Cladosporium mansonii*. The disease responds readily to the usual antimycotic applications.

Keratosis Nigricans Palmaris—The third member of this group is *keratosis nigricans palmaris*, which has been reported only from several different points in Brazil. It is characterized by pinhead size, deep brown or black papules on the palms, the wrists, the palmar and lateral surfaces of the fingers and the

interdigital spaces of the hands. The papules gradually coalesce to form slightly raised plaques of irregular contour and with polycyclic borders. There is no itching, erythema or signs of inflammation. It is due to *Cladosporium werneckii*, which shows branched mycelia and oval spores in potassium preparations of the scales and grows easily on the usual mediums as a brown or deep green moist colony. The disease has been reproduced in the guinea pig and in man from these cultures (Sartory, Rietman and Meyer.²²) The disease responds easily to treatment.

DERMATOMYCOSES CAUSED BY THE ALEURIOSPORE GROUP

The only member of the group well enough studied to be mentioned here is *tinea albigena*, otherwise known as *khi-huen*. The disease has been known scientifically since the later years of the last century and is widespread in southern Asia. It has been reported from southern India, Indo-China, Ceylon, New Guinea, Borneo, Sumatra, Java and Brazil.

The eruption is localized almost exclusively on the palms and soles. Three stages have been described by Nieuwenhuis²³ the vesicular, the chronic and that of depigmentation and atrophy. It begins as an itchy papule which is quickly transformed into a vesicle surrounded by a narrow zone of intensely acute inflammatory reaction. Repeated attacks of new blisters occur until large areas of the palms and soles are involved. The disease is undoubtedly spread by scratching, which tears off the top of the vesicle and disseminates its serous contents. Since there is a tendency to spontaneous recovery, the disease becomes chronic with the production of thick, fissured and very painful calluses at the site of the vesicle. The disease may be so extensive on the soles that certain individuals, and especially Europeans, are unable to walk or work. In the chronic stage, although itching is present, it is not nearly so severe as in the vesicular, or acute, stage. Gradually the disease penetrates deeper into the skin until the pigment function is completely destroyed. Permanent and complete depigmentation of these areas is the result. Langeron²⁴ mentions a fourth stage in which the eruption, after many years of chronicity, may spread to the wrists, forearms, backs of the hands and feet, and the ankles. The nails may also be involved.

The eruption is symmetrical and is due to a simultaneous contagion, rather than a trophic disturbance, as was originally thought.

The parasite is a hyphomycete with aleuriospores and belongs to the genus *Glenospora*. It is called *Glenospora albicans* and it grows very slowly on Sabouraud's medium as a rough surfaced colony, which has a white color at first and later a lighter brown.

The disease should be thought of because of its localization to the palms and soles. It shouldn't be confused with acromycosis, herpes circinata, tokelau pinta, *pityriasis versicolor*, *keratosis palmaris et plantaris hereditaria*, arsenical keratoses or tylotic eczema. The different stages of the production of the fully developed disease, plus the permanent depigmentation and the laboratory studies, should make the diagnosis easy if the disease is kept in mind.

Nieuwenhuis²⁵ recommends that the treatment be begun early and be carried out vigorously and continuously in order to cure it before the chronic stage is reached. He uses wet compresses renewed at frequent intervals during the day and night for several days, of 10 per cent chrysarobin in equal parts of alcohol and ether. Tincture of iodine painted on in thick layers for fourteen days may also be used. In the chronic stage the horny masses must be removed before one applies this treatment.

TROPICAL DERMATOMYCOSIS PROBABLY DUE TO TRICHOPHYTONS

Tropical Ringworm of Sabouraud—This is the name given by Castellani to a skin disease found by Sabouraud in patients coming back to France from Indo-China, Tonkin and Japan. Castellani²⁶ reported the same eruption in Ceylon and now the disease is believed to be widespread in the hot, humid portions of the Far East.

The eruption is intensely pruriginous and very chronic. It begins on the uncovered parts of the body and especially on the legs with the formation of erythematous round spots whose surfaces are covered with a very fine layer of scales. The spots enlarge peripherally, clear in the center and form complete or incomplete rings, resulting finally in large plaques with polycyclic borders. The centers of the plaques are brownish and smooth. The scaly borders may be slightly elevated or they may merge into the surrounding normal skin. At times vesicles and papules form on the borders of the lesions. Itching increases with the spread of the disease, and in long standing cases the borders of the plaques become distinctly lichenified.

Curved, banana shaped, mycelial filaments without the double contoured membranes seen in true trichophytosis are found in large numbers in potassium preparations of the scales. Between the mycelia occur oval or round spores of various sizes. The parasite has never been cultured and never transmitted from man to man or to laboratory animals.

It is almost mandatory that patients afflicted with this disease leave hot, moist climates before the disease will respond to treatment. The usual antimycotic preparations will then suffice.

Although not definitely proved, it is probable that this is a true dermatomycosis.

The second member of this group, *tinea nigrocinata*, was described by Castellani²⁷ in Ceylon. It is characterized by the formation, only on the neck or scrotum, of black annular lesions with elevated and often crusty borders. The lesions are all about the size of a large pea. The skin surrounding the lesions is pigmented a deep brown for a distance of 1 to 2 centimeters. Potassium preparations of the scales show mycelial elements and round spores both with double contoured membranes. No cultures or inoculations succeeded.

The disease is benign and may disappear spontaneously or after the application of mild forms of iodine, chrysarobin, ammoniated mercury or other medications.

The mycetomas, which are so prevalent in the tropics, will be discussed in another portion of this symposium.

MEDICAL ENTOMOLOGY IN RELATION TO TROPICAL DERMATOSES

MAXIMILIAN E. OBERMAYER, MD
LOS ANGELES

Diseases due to animal organisms, especially the arthropods, vary somewhat in geographic distribution and with climatic conditions, yet most of such dermatoses which commonly occur in the United States are also encountered in all other parts of the world and knowledge of the disorders seen at home will aid in the management of such dermatoses in the tropics. Consequently a brief outline of the important diagnostic and therapeutic points relating to these diseases appears indicated, particularly since most of the information derived from experience with arthropod borne disease in this war is in the hands of the military personnel and little of it has been published. Some recent data, published mainly by British investigators, and information obtained from the Army Medical Museum in Washington, D. C., and from private sources are incorporated in this article.

Of diseases caused by arthropods the following deserve attention:

DISEASES BORNE BY MEMBERS OF THE CLASS ARACHNIDA

DISEASES CAUSED BY MITES AND TICKS

Scabies—Human Scabies. Routine knowledge of this important and ubiquitous disease will be taken for granted. Only some less generally known points which may be of service will be covered.

Infestation is occasioned by more or less intimate contact with an infested person. Sleeping with a person with the disease or in a bed recently occupied by such a person is the most common method of contracting the disease, but in a considerable proportion of cases the infestation is of venereal origin. However, so transitory a contact as a simple handshaking may suffice to transmit the disease. Scabies is so highly transmissible that it has been an important source of loss of man-days in all armies in all wars. Scabies should be considered in every case of pruritic eruption, especially if the hands and the genitalia are involved. Once the diagnosis is made, men who have been in daily contact with the patient should be examined.

To recover *Sarcoptes scabiei* from a lesion needs an experienced examiner. Under field conditions the presence of burrows or papulovesicles in their characteristic location and the history of nocturnal pruritus should suffice to make the diagnosis of scabies. The penile and scrotal lesions commonly are infiltrated papules, and the diagnosing of scabetic papules as lesions of early syphilis and vice versa, is a deplorable and unfortunately not uncommon error. On the other hand since scabies is frequently venereal in origin the simultaneous presence of the two diseases is not improbable.

Latest research in the treatment of soldiers has shown that of the many medicaments in common use for scabies only two, sulfur ointment and benzoin

This paper is a symposium on "Tropical Diseases of the Skin," published under the auspices of the Section on Dermatology, I. Mellanby, Kenneth Johnson, C. C. and Parkland, V. C. T. Treatment of Scabies Brit. M. J. 2, 1 (July 4) 1947.

25 Jeanselme. Cours de dermatologie exotique, p. 236.

26 Castellani quoted by Langeron, p. 374.

27 Castellani, quoted by Langeron, p. 375.

zoate, are satisfactory. Benzyl benzoate, the main ingredient in Peruvian balsam, was found to be fully effective in the form of a lotion or emulsion. A 10 per cent sulfur ointment or a vanishing cream containing 10 per cent of sulfur applied three times in routine fashion is efficacious, while sulfur lather preparations are not. Tests with preparations containing rotenone have been unsatisfactory; furthermore, derris root emulsions are notorious for causing dermatitis. Investigations suggest that pyrethrum extracts are not particularly valuable for treating human scabies, and pyrethrum too is well known as an epidermal sensitizing agent.

The case of ointment versus liquid preparations may be stated thus. If the patient applies the medicament himself, the use of ointments, even though they are "messy," is safer, for it has been found¹ almost impossible for a patient to apply either liquid preparations or creams satisfactorily to himself.

The classic method of treating scabies made mandatory a thorough scrubbing of the skin under a hot shower with liquid soap and a flesh brush, to remove the tops of all lesions. While the long soak in a hot bath followed by scrubbing is a desirable feature if soldiers are treated in a hospital or sick bay, it is useful to know that treatment can be carried out successfully when such facilities are not available,¹ a point of great practical importance in desert warfare.

Prescriptions 1, 2 and 3 are recommended for routine use. I have used the ointment given in prescription 1 for years with satisfactory results.² As an after-treatment the application of a simple antipruritic shake lotion is desirable. The formula³ given in prescription 4 is helpful. Under no circumstances should the course of treatment be repeated unless the presence of a living organism is demonstrated, since the dermatitis resulting from overtreatment (especially with sulfur) may occasion a greater loss of man-days than the infestation.

The most frequent complication of scabies is pyogenic infection, especially under field conditions, it tends to

be more severe in seborrheic individuals and is best treated with a 5 per cent sulfadiazine or sulfathiazole cream.

Scabies of Animals. Organisms related to the acarus responsible for human scabies cause a similar disease in animals and birds which may be contracted by man.

Scabies of the horse. This disorder is of common occurrence in military stables. Soldiers caring for

horses with scabies frequently contract the disease, which has a short incubation period, signs often appear on the day infestation occurs. Differentiation from human scabies rests on the absence of burrows and the differences in location and appearance of the lesions. The lesions, which are bright red, conical, follicular papules, usually capped by a hemorrhagic crust, appear on the flexor surfaces of the arms, the breast and the

PRESCRIPTION 3—Benzyl Benzoate Emulsion

	Gm or Cc
Rx Benzyl benzoate	200 0
Stearic acid	20 0
Triethanolamine	5 0
Water	q s ad 1 000 0

Melt the stearic acid with the benzyl benzoate on a water bath. Mix the triethanolamine with half the quantity required of warm water and pour into the stearic acid benzyl benzoate mixture cooled to about 30 C. Shake to form an emulsion and add enough water to produce the required volume.

PRESCRIPTION 4—Antipruritic Shake Lotion

Glycerin	15 0
Water	70 0

abdomen down to the belt line, the genitalia are almost never involved. A peculiar feature is the appearance of an urticarial wheal when the lesions are scratched (factitial urticaria). The disorder runs a mild course and subsides spontaneously. Ordinary antiscabietic treatment may be used if necessary.

Scabies of the dog. This disease is frequently encountered in tropical and subtropical countries. In human beings it is characterized by the appearance of red macules and papules, occasionally capped by minute vesicles, urticarial reactions are common. The location of the eruption depends on the point of contact, the neck and the upper part of the chest are most frequently involved, but the cheeks, postauricular region and scalp are also common sites. The disorder responds promptly to antiscabietic therapy.

Scabies of the cat. This disease, most common in countries in which neglected cats abound, is caused by a smaller parasite which is not strictly an acarus. On human patients the lesions, which are similar to those of strophulus, appear as small papules capped by a minute vesicle. Antiscabietic treatment is not required, the application of an antipruritic shake lotion is usually sufficient.

Rat Mite Dermatitis.—The disease is caused by *Lyponyssus bacoti*, which is of significance because it is a carrier for the virus of endemic typhus fever. The lesions consist of wheals, papules and vesicles, which may become infected as a result of scratching. In adults the eruption is usually limited to the ankles, but it may appear in small patches elsewhere. Buildings infested with the mites must be gone over by an exterminator squad.

Food Mite Dermatitis.—Other mites closely related to acari and predominantly of the *Tyroglyphus* variety, are present in such materials as cheese meal, copra, dried fruit and linseed oil. Persons such as pickers

of dock workers, who come in contact with infested material may show a pruritic eruption which is known variously as "grocers' itch" or "copra itch." The lesions, small, pointed erythematous papules which itch intensely, develop on the parts of the body which come in contact with the material, the extensor surfaces of the hands and forearms are chiefly involved. The application of an antipruritic shake lotion is therapeutically sufficient.

Acrodermatitis Urticarioides.—Grain itch is caused by a macroscopic, grayish yellow mite, *Pediculoides ventricosus* which lives on the larvae, caterpillars and chrysalis of various organisms noxious to grain, the eruption occurs among men who sleep on infested straw or straw mattresses. The extent of the eruption depends on the number of organisms and the sensitivity of the patient. In mild infestations it is limited to the regions in most intimate contact with the infested material, in the more severe forms of the disease the entire trunk, the neck and even the face may be involved. The lesions are small bright red papules often capped by a vesicle which becomes a pustule. The larger lesions are somewhat urticarial. All the papules may appear hemorrhagic, but they pale out completely on glass pressure. Diagnosis is sometimes difficult because the eruption may resemble varicella, and it may be accompanied by such mild constitutional symptoms as fever and slight albuminuria. However, the characteristic umbilication of the varicella vesicles is absent and the pruritus is intense. The history of contact with straw is suggestive, especially if the troops have been billeted about farms. Treatment consists in application of an antipruritic shake lotion. Infested straw ticks should be burned.

Wood Tick "Bites".—Ticks (*Ixodes*) are readily visible organisms which penetrate the epidermis by means of a lancet shaped under lip until the head is more or less embedded in the skin. The penetration of the tick is usually unnoticed by the patient, a circle of erythematous reaction appears only if the patient is hypersensitive. Ticks are parasites of cattle, dogs, rabbits and man. In temperate climates there is a seasonal prevalence in May, June and July. Men should be examined carefully for ticks because of the role of the parasites in spreading Rocky Mountain spotted fever, tularemia and exanthematous fever of the Mediterranean. São Paulo typhus and Central African relapsing fever. Soldiers should be instructed not to remove ticks with the bare fingers for if an attempt is made to remove the organism by force the lower jaw is left in the wound and may cause a prolonged purulent discharge unless removed surgically. It is better to suffocate the tick by the application of a material such as liquid petrolatum, glycerin or kerosene. With such treatment the head is spontaneously retracted in several minutes or hours and the tick falls off.

Trombidiosis.—Jigger bites (*trombidiosis*) are produced by larvae (*Leptus autumnalis*, harvest mites, redbugs) of several members of the *Trombidia* family which live on flowers, grasses, shrubs and grain (buckwheat) and on the ground near such vegetation. The larvae live independently and feed on various animals (mice, snakes and man). The organisms, which are active from spring to fall, produce lesions at the point of contact, they commonly attack the skin below a tight constriction, such as a garter or a belt. The initial

erythematous macule is followed by an intensely pruritic papule surrounded by an erythematous halo, which may be hemorrhagic, the larva may sometimes be seen in the center of the papule as a point of brick red color. The lesions may be of other types, e. g. minute hemorrhagic puncta, urticarial wheals or lesions resembling lichen urticatus. The bite itself is usually not noticed, the patient's attention is aroused by the intense itching which is especially evident at night when the patient has become warm in bed. The larva falls off in forty-eight hours or less and is consequently gone when the patient seeks medical attention. The lesions persist for an uncommonly long time. The secondary infection which usually ensues is often extremely persistent and the response to treatment is less satisfactory than with other forms of secondary pyogenic infections. Occasionally there is initiated a chain of generalized skin sensitization with eczematous "id" lesions which require weeks or months to heal.

Trombidiosis is of military importance because partial disabilities from scratch infection may assume large proportions among troops in warm climates. In addition, in the Far East trombiculae present another and more serious danger, for the organisms transmit the Tsutsugamushi group of Rickettsial diseases namely the Japanese River fevers which are identical with Malayan scrub typhus.

PRESCRIPTION 5—Compound for Trombidiosis

	Gm or Cc
R Benzocaine	20
Flexible collodion	150
(Bottle with rod in stopper)	

Vigorous measures for the prevention of jigger bites should be taken in regions where there is thick, tall grass, especially during the late summer months. Prophylaxis consists in the application of 5 per cent sulfur in talcum as a dusting powder. A warning about the possibility of sulfur dermatitis should be given especially in the case of men with dry or poorly pigmented skins.

Thrice daily applications of a 2 per cent rotenone solution (such a preparation is available from the Abbott Laboratories) have been used for treatment. This therapy has the disadvantage that dermatitis frequently ensues, especially when the solution is applied to the genitalia. Application of an antipruritic shake lotion will allay the itching. Twice daily application of the preparation given in prescription 5, recommended by R. L. Sutton Jr., has proved effective.

It is essential to recognize secondary pyogenic infections early and to treat them by local applications of a 5 per cent sulfathiazole or sulfadiazine ointment. It is also important to protect the sites of the lesions from contact with rough woollen clothing, so that development of contact dermatitis may be prevented once the complication has developed the man should be sent to a hospital, because field conditions do not allow the limitation of activity necessary to overcome the cutaneous irritation.

SPIDER "BITES"

The most important poisonous spider—and the only one found in the United States—is the tarantula, *Latreutes mactans*, known as the black widow. The spider is commonly found on refuse heaps in buildings.

stables. Pain in the region of the bite and intense regional swelling may be followed by such grave constitutional symptoms as spastic cramps of the extremities, rigidity of the abdomen with nausea and vomiting, headache, ringing in the ears, dizziness, pain throughout the body, a rise in blood pressure of 30 or 40 mm. and a state of anxiety. Generalized toxic erythemas are not uncommon. The bites may be inflicted on any part of the body but frequently occur on the genitalia or buttocks through exposure in an outdoor privy.

Treatment, according to Frawley and Ginsberg, should consist in bed rest, a soap solution enema, increase in the intake of fluids, intravenous administration of 20 cc. of a 10 per cent solution of magnesium sulfate (to combat hypertension and spasticity of the muscles), hypodermic administration of morphine (to control pain) and peroral sedation. Tincture of iodine should be applied immediately to the wound, followed by wet dressings with potassium permanganate (1:8,000).

DISEASES BORNE BY MEMBERS OF THE CLASS INSECTA

DISEASES CAUSED BY LICE AND BUGS

Insects are of much greater importance in military medicine than in civil practice. Insects spread many epidemic diseases, and their "bites" may cause disability of formidable duration if adequate measures for the prevention of secondary eczematization and pyogenic infection are not instituted immediately after the "bite" is inflicted.

In general an insect "bite" appears as a central punctum in an initial macule, wheal or papule, the degree of inflammatory reaction varies with individual hypersensitivity. Insect "bites" often appear as asymmetrical groups and it is best to consider them as a diagnostic possibility in every pruritic papular and urticarial eruption.

Pediculosis—It appears certain that lice, the agents of pediculosis, leave a febrile patient and try to find other hosts, a point of epidemiologic importance. It is also known that small lice may be distributed in the open air by wind and may be blown on to the outer garments of those engaged in dealing with infested persons. It has been shown that head lice may be acquired from the upholstered backs of seats and chairs, from brushes and combs and by passage from hat to hat (e. g. in schools or mess rooms). Similarly, the body louse may spread when groups huddle together for warmth.

The military significance of pediculosis is illustrated by the statistics showing that during World War I (in 1917) the casualty clearing stations of the British Second Army admitted more than 10,000 men for inflammatory disorders of the skin, caused mostly by lice.

1 Pediculosis Corporis *Pediculosis corporis* is the most important of the three forms of this infestation because the body louse, its agent, transmits epidemic typhus, trench fever and recurrent febrile spirochetoses. The body louse is better called the clothing louse, since it inhabits the clothing and only feeds on the skin, its eggs are laid about the seams of clothing, where they should be searched for. In most instances the patient presents only excoriations usually

linear, on portions of the body where the clothing is in intimate contact, especially the shoulders and about the waist and buttocks. The incidence of infestation increases sharply in men who have little opportunity to bathe, especially if quarters are crowded. The spread of diseases by the clothing louse is aided by the European custom of popping lice between the thumbnails and the American and Australian habit of crushing them with the teeth. Since the spirochete of the recurrent febrile spirochetoses is transmitted by inoculation incident to rupturing of a louse and cannot be transmitted by the louse's "bite," these customs should be discouraged.

Treatment consists in autoclaving of the clothing for fifteen minutes and thorough scrubbing of infested men with soap and brush. Secondary pyogenic infection or scratch dermatitis must be treated.

2 Pediculosis Capitis The only important complication of this otherwise harmless infestation is the secondary pyogenic infection which is produced by scratching, usually on the nape of the neck or the occipital and temporal regions, and is often accompanied by enlargement of the posterior cervical nodes.

The older methods of treatment by applications of equal parts of kerosene and olive oil, acetic tincture of

larkspur, N. F. VI, or 1:500 mercury bichloride solution are gradually being replaced by other methods. I use cuprex (a proprietary copper compound) solution. Busvine and Buxton⁴ reported great success from the use of a 1 per cent rotenone emulsion or the compounds given in prescriptions 6 and 7. They recommended applying the compound once, with spoon or pipet, to four areas of the scalp on each side and allowing it to remain for ten days before shampooing, 8 cc. of the material per patient is sufficient. Patients' caps and helmets, of course, must be sterilized. The use of vinegar to soften the gelatinous coating that attaches the nits to the hair should be discouraged, contrary to popular belief, it has been shown that the substance is not dissolved after soaking in a 10 per cent acetic acid solution for several days.⁴ If many men are infested it is advisable to clip the scalp routinely.

3 Pediculosis Pubis Infestation with the crab louse would be insignificant except for the discomfort produced by the itching were it not for the disabilities which result from irritating methods of treatment. Neither the old blue ointment nor rotenone preparations should be used, and shaving of the pubic hair, which causes considerable discomfort during the early stage of regrowth, is unnecessary. The best method of treat-

⁴ Buxton, P. A. *The Louse*. Baltimore: Williams & Wilkins Company, 1940.

ment consists in application of 1 to 2 ounces of cuprex. The solution is rubbed into the involved regions and ten minutes later rubbed in again, it is allowed to act for one hour, and the region is then carefully washed with soap and water. Pediculi on the eyelashes may be removed by contact with an applicator saturated with cuprex for one minute. If cuprex is not available, mercury bichloride 1:500 in 70 per cent alcohol may be applied twice daily, but it should be remembered that the skin is occasionally sensitive to mercury and that eczema may result. Failures often result from not paying sufficient attention to the perianal hairs.

BEDBUG "BITES"

Cimex lectularius is of epidemiologic significance as the transmitter of the recurrent febrile spirochetoses. Hence the remarks on the danger of inoculation by rupture of lice apply to rupture of bedbugs as well.

The lesions produced by *Cimex* are usually firm, conical papules. However, if hypersensitivity is pronounced, large, sometimes hemorrhagic, bullae may form. The grouping of lesions in pairs and triplicates, fairly close together, is a characteristic feature.

Treatment consists in extermination of the insects. The only method which gives absolutely certain results is fumigation with hydrocyanic acid. Mercury bichloride solution 1:500 kills the eggs when poured into cracks and crevices of furniture, floors and walls, and fumigation with sulfur will kill the parasites. A good general insecticide, cheap and harmless, which may be used for spraying floors and walls, is made by dissolving three parts (by weight) of soft soap in fifteen parts of water and slowly adding kerosene while stirring constantly until no more will emulsify.⁴ This concentrated emulsion can be stored in bottles, it is diluted 1:20 for use.

DISEASES CAUSED BY FLEAS

Flea "Bites"—Fleas are chiefly important intermediary hosts for the agents of such serious diseases as bubonic plague, exanthematous and murine typhus and various bacteria, tropical protozoa and worms. The flea jumps on and off the host and does not confine itself to one host. In addition to human fleas, many varieties of animal fleas attack man when hungry, those of most interest to man are the fleas of dogs, cats, rats and squirrels. Confusion arises from the frequent erroneous designation of these fleas, in sandy regions, as "sand fleas," a term which is correct only for the penetrating, strictly tropical sand flea (*chigoe*). Animal fleas infest buildings or even the sand itself in sandy areas and attack human beings.

A flea puncture results in the formation of an erythematous macule or wheal with a central hemorrhagic punctum (*purpura pulcosa*). Giant urticaria may result if the patient is hypersensitive. Some persons are immune.

Treatment consists in the application of an anti-pruritic shake lotion.

Chigoe—Chigoe infestation, or dermatophylia, is a cutaneous disorder produced by the sandflea, or chigoe, which is encountered chiefly in Central America, the West Indies, the northern part of South America, Africa and India. It is principally a disease of the tropics but occasionally occurs in the temperate zone. Chigoe infestation is known under various native designations, of which nigua and chigoe itch are the most common. In the United States trombidiosis, or jigger

bites, is frequently confused with dermatophylia, although the two disorders are caused by entirely different organisms and run different clinical courses.

The minute insect which is responsible for dermatophylia belongs to the family Sarcopsyllidae and is named *Sarcopsylla* (*Pulex*, *Tunga*, *Dermatophilus*) penetrans, it is the most completely parasitic of the species of fleas. In appearance it resembles *Pulex irritans*, the common flea, except that its proboscis is longer. Sand fleas live in dry, sandy soil and feed on the blood of various animals. After impregnation, the female attaches itself to the skin of man and that of many animals, especially swine, rats and mice, and pierces it obliquely, so that all except the last two segments of its body become embedded. Sucking blood for several days increases the size of the insect to several millimeters. If left undisturbed, it remains on the host and lays a large number of eggs, which hatch in eight days and after three weeks become mature adults.

The cutaneous lesion produced by the sand flea is at first a shallow burrow, at the opening of which the posterior part of the insect is visible as a brownish red dot. Later there develops a pruritic papule, several millimeters in diameter, which suppurates. Abscesses and ulcers, accompanied by lymphangitis, may be formed, such ulcers are resistant to treatment. Secondary infection, gangrenous or tetanic, may necessitate amputation. Lesions as a rule are located on the feet, at the corner of or beneath the free margin of the toe nails or on the ankles, however, since soldiers often sleep on the ground sites other than the feet (e. g. the anogenital region) are often affected.

Treatment depends on the stage of the disorder. If suppuration has not yet taken place, the affected part should be thoroughly cleansed with soap and water and the insect skillfully extracted by means of a blunt, heated needle. Great care should be taken not to rupture the flea while attempting to extract it, because if part of it or some of its eggs remain in the burrow, subsequent suppuration is inevitable. If suppuration has occurred or if the attempt to remove the insect is only partially successful, the cavity should be subjected to forceful cleansing and cauterization with pure phenol followed by the immediate application of alcohol. The wound should be dressed with a 5 per cent sulfathiazole or sulfadiazine cream.

Infestation can be prevented by putting up camp away from chigoe infested localities. The neighborhood of native villages should be avoided, and the ground should be swept or fired. Walking barefoot should be discouraged when the disorder is prevalent.

DISEASES CAUSED BY OTHER INSECTS

Other insects which attack human beings are gnats, mosquitoes, bees, wasps and flies. The resulting lesions are macular, papular, hemorrhagic or urticarial. If the patient is hypersensitive, the reaction may be so extensive as to simulate angioneurotic edema, and severe constitutional symptoms may even be present. The larva of the bot fly produces painful inflammatory nodules, and the "bite" from the black fly causes the formation of a pruritic nodule often with the accompaniment of swelling of the regional lymph nodes and regional pain and stiffness. The reaction is often delayed for twelve to twenty-four hours and persists for days.

YAWS, CUTANEOUS LEISHMANIASIS
AND PINTAHOWARD FOX, MD
NEW YORK

Of the three diseases described in this communication yaws and cutaneous leishmaniasis are prevalent in many parts of both hemispheres. Pinta is largely confined to the American tropics. Few members of our armed forces are liable to contract either yaws or pinta as these diseases are due to lack of personal hygiene and are not usually acquired through insect vectors. However, our medical officers in certain tropical regions will doubtless have to render medical aid to native populations and will then see many cases of these diseases.

Cutaneous leishmaniasis is however contracted both by personal contact and by the bite of one of several species of *Phlebotomus* or occasionally of other insects. It is therefore probable that some of our armed forces will be infected by this disease.

Yaws and pinta are confined almost exclusively to the tropics, whereas cutaneous leishmaniasis is seen in both tropical and semitropical regions.

YAWS

Yaws is the term used in British and American colonies for the disease known as *frambesia tropica*. In French speaking colonies the term *pian* is used. Yaws is an infectious disease caused by *Treponema pertenue*, an organism which is morphologically identical with the spirochete of syphilis. Its discovery by Castellani followed shortly after that of *Treponema pallidum*. The disease is confined almost entirely to the Negro race. The geographic distribution is widespread in parts of equatorial Africa, many islands of the Pacific including the Philippines, the Malay States, Burma and Thailand. In the western hemisphere it is extremely prevalent in Haiti, Santo Domingo and Jamaica as well as in some equatorial areas of South America.

Yaws resembles syphilis in some respects but shows enough differences for it to be regarded as a separate, though closely allied, disease. Infection with yaws is almost invariably extragenital, the initial lesion often occurring on the leg. The disease is probably acquired most often through personal contact, just as impetigo contagiosa is carried from one child to another. Ideal conditions for this method of transmission of yaws exist among native races in tropical regions who sleep together in crowded huts and wear little or no clothing. There is no doubt that yaws may also be transmitted by flies. In Jamaica Kumm and Turner noted swarms of hippelates flies on lesions of yaws and were able to find 300 spirochetes in the diverticulum of a single fly. It is thought that the infection is simply due to regurgitation by the flies when they alight on an abraded surface.

Yaws is acquired most often in childhood. Transmission through the placenta is however unknown. Yaws

is never congenital and fails to show any stigmas such as saddle nose, Hutchinson's teeth or interstitial keratitis which would correspond with those of congenital syphilis. In India, Powell observed 17 pregnant women in the florid stage of secondary yaws and found that all gave birth to babies who remained free from yaws.

Another feature which differentiates yaws from syphilis is the complete absence of lesions of the mucous membranes in the early (secondary) stage. There are no vaginal mucous patches, which accounts for the absence of venereal infection. However, in the late or tertiary stage destructive ulcerating gummas may be seen in the mucous membranes.

The cutaneous manifestations of secondary yaws show some striking differences from those of syphilis. The initial lesion, or "mother yaw" which is often absent, is of the same type as the common frambesiform eruption except for its much greater size. The typical secondary eruption appears about six weeks to three months after infection and consists of small papules, some of which disappear without further change, whereas others coalesce, soften and form rather typical amber colored crusts. This does not resemble any manifestation of syphilis but may be mistaken for impetigo. The eruption may be generalized and profuse or show a tendency to be localized about the mouth and in the anogenital region. At times the lesions form circles, which are spoken of as "ringworm yaws," though this does not resemble the annular papular syphilitid with its delicate raised border and hyperpigmented center, which is so characteristic of the Negro race. The eruption lasts from one to two years or even longer at times and disappears spontaneously without leaving any permanent trace.

Whereas the macular eruption (roseola) is the commonest one in syphilis, it is nearly always absent in yaws. This is not due to the difficulty in detecting it on the dark skin as those who have had experience with syphilis in Negroes will testify.

A peculiar eruption of yaws occurs on the soles and at times on the palms and is spoken of as "crab yaws" in the West Indies. This term is used to describe the difficulty in walking (like a crab) especially when the lesions are secondarily infected with pyogenic cocci. This manifestation consists of hyperkeratoses which are usually bilateral and which occur frequently toward the end of the secondary period. That it is an undoubted manifestation of yaws is proved by the presence of spirochetes beneath the scales and by the response to anti-syphilitic treatment.

An infrequent eruption of yaws consists of pinhead size papules in groups. This has been called a "keratoid" eruption on account of its supposed similarity to keratosis pilaris. In my opinion it has a closer resemblance to lichen scrofulosorum.

Yaws again differs from syphilis by the complete absence of iritis or iridocyclitis. This is rather striking as syphilitic iritis is decidedly more common in the Negro than in the white race. There is also an absence in yaws of alopecia either of the diffuse or so-called "moth eaten" type. The statement frequently made that itching constitutes a feature of differential diagnosis between syphilis and yaws is unwarranted in my opinion. It is agreed by all that the cutaneous lesions of syphilis are essentially nonpruritic and I think the same is true of yaws.

The late destructive or tertiary manifestations of yaws are clinically indistinguishable from those of syphilis.

This paper is a symposium on Tropical Diseases of the Skin as published under the auspices of the Section on Dermatology and Syphilology.

Excellent articles on pinta have recently been published by V. Pardo Castello and Ismael Ferrer (*Arch. Derm. & Syph.* 45: 843 [May] 1942) and by Herman Beeraman (*Am. J. M. Sc.* 205: 611 [April] 1943).

Full descriptions with bibliography of the three diseases described may be found in *Stitt's Diagnosis, Prevention and Treatment of Tropical Diseases*, 6 Philadelphia: Malinkson Company, 1943, edited by Col. Richard P. Strong. Also chapters by Howard Fox in *Clinical Tropical Medicine*, edited by Z. Beresovitz, New York: Paul B. Hoeber, Inc., to be published.

and consist of gummas of the skin and mucous membranes and osteoperiostitis of some of the long bones, synovitis and tenosynovitis, often producing severe mutilation in neglected cases. The tendency of secondary manifestations of syphilis to be followed by a long period of latency is not the rule in yaws, as in this disease the late changes may follow soon after or even before the secondary lesions have disappeared.

Yaws is a milder infection than syphilis as is shown by its comparatively infrequent involvement of the central nervous and cardiovascular systems. The majority of investigators have failed to find abnormalities in the spinal fluid in yaws, and the majority also consider tabes and paresis to be nonexistent or at least extremely rare in yaws. Similar opinions are expressed about lesions of the cardiovascular system. Although Choisser found 10 cases of aneurysm in a series of over 700 necropsies in Haitian Negroes, there was no positive proof that they had not been caused by syphilis. The chief evidence was based on the fact that these lesions were found in natives who had lived in rural districts where yaws rather than syphilis was extremely prevalent. The prognosis as to life in yaws is good, Manson-Bahr stating that "judging from the statistics collected by Nicholls, the mortality must be very small indeed."

The clinical diagnosis of yaws is usually easy in the secondary stage (frambesiform eruption), though in the late stage it becomes difficult or impossible. Spirochetes can be demonstrated with great ease in the frambesiform lesions after removal of the crusts. The organisms have also been found in the lymphatic glands, spleen and bone marrow. They have, however, never been demonstrated in the blood, though successful inoculations have been made in monkeys from the blood of persons suffering from yaws. Differences between syphilis and yaws have been noted in bones on roentgenographic examination, yaws showing a high incidence of osteoporosis.

Animal experiments with monkeys and rabbits have added to our knowledge of yaws. It has often been possible to establish the diagnosis of yaws by inoculation of monkeys, in which a typical frambesiform eruption has been produced. According to Pearce and Brown, a differential diagnosis between syphilis and yaws can usually be made by intratesticular inoculation of rabbits. Inoculation with *Treponema pallidum* usually produces a hard lump, with frequent dissemination to the lymphatic glands, bones and viscera. On the other hand, inoculation with *Treponema pertenue* produces a local reaction, spoken of as a granular orchitis.

Animal experimentations have also added to our knowledge of immunity in yaws. There is eventually complete cross immunity between syphilis and yaws, though there are differences in the immune state in the two diseases. Thus Schobl states that syphilis produces an immunity to itself quicker than it does to yaws and much quicker than yaws does to itself. Before the period of cross immunity is established it is possible for man and susceptible animals to acquire both diseases.

Serologic reactions with either complement fixation or flocculation tests are of no value in differential diagnosis, as syphilis and yaws respond similarly. Both diseases give close to 100 per cent positive reactions in the secondary stages with a gradual lessening of such reactions in the later stages.

Yaws responds unusually well to arsphenamine (or allied drugs) and to bismuth compounds, though mer-

cury does not act satisfactorily in the secondary stage, a feature which is considered diagnostic by Castellani. In the early stages the disease may be permanently cured by three successive injections of neoarsphenamine, though much more treatment is required in the late stage. Oral administration of acetarsone has been used with success, but, as Strong says, the expense of a complete course may equal that of three injections of neoarsphenamine. Bismuth has been widely used on account of its low cost for mass treatment of native populations.

There are three unusual diseases which in many cases are considered to be sequelae of yaws. They are gangosa, goundou and juxta-articular nodes. Gangosa is a severe destructive nasopharyngitis, a typical case being usually described as presenting a funnel shaped opening with the upper lip as its lower border. The nasal septum and surrounding soft parts, the palate and even the eyes may be destroyed. It is thought to be a sequela of yaws, because it occurs in areas where yaws is endemic. Gangosa is seen in parts of equatorial Africa, in Guam, in the Fiji Islands and in the island of Dominica in the West Indies. The disease occurs in untreated persons and is practically incurable.

Goundou is an exostosis beginning in the nasal process of the superior maxillary bone, which forms a hard painless tumor, projecting downward and outward. It may attain the size of an apple and interfere with vision or destroy the eyes. The disease was first observed in Africa by McAllister, who spoke of the affected natives as "horned men." Goundou is thought by many to be a sequela of yaws because it often follows the frambesiform eruption and because heavy inoculations with *Treponema pertenue* fail to produce ordinary lesions of yaws. Some doubt the relationship to yaws and consider the disease to be osteitis deformans or other type of disease of the bone. The treatment is surgical.

Juxta-articular nodes consist of painless, hard enlargements occurring usually in the neighborhood of the larger joints, especially the elbows and knees. Similar lesions occur as late manifestations of syphilis. Spirochetes have been demonstrated both in the nodes supposedly due to yaws and in those due to syphilis. The course of the disease is exceedingly chronic but it responds slowly to antisyphilitic treatment. If desired the lesions can be surgically removed.

CUTANEOUS LEISHMANIASIS

There are two types of cutaneous leishmaniasis which differ sufficiently to warrant their being considered as separate diseases. They are oriental sore, a purely cutaneous disease of the Old World, and mucocutaneous leishmaniasis, seen only in the Western Hemisphere. These two forms of the disease which involve the skin are caused by protozoa which are morphologically similar to each other and to the organism which causes kala-azar. They are round or oval bodies with a large kinetoc nucleus and a small rodlike nucleus, and in cutaneous lesions they are found chiefly in endothelial cells and large mononuclear leukocytes. They can be demonstrated microscopically in scrapings from the edge of an ulcer or the under surface of a biopsy specimen stained by Wright's method. They can also be cultivated and are flagellated obligatory aerobes. However, in the so-called relapsing cases of oriental sore it is difficult or impossible to demonstrate the organisms.

1 *Oriental Sore*—Known also as Aleppo boil, Biskra button and Delhi sore, oriental sore is confined to the Eastern Hemisphere and has a wide geographic distribution. It is endemic on the Mediterranean coast of Africa and in Syria, Palestine, Armenia and the southern and eastern parts of Asia, including Iraq, Iran and parts of India and China. In Europe it occurs chiefly in Greece, Italy, Sicily, Cyprus and Crete.

The disease is transmitted both by the bite of several species of phlebotomus and at times by the common house and stable fly and also by personal contact. Both of these methods of transmission have been repeatedly proved. Dogs, especially those with lesions about the nose, may act as reservoirs of the parasites.

The incubation period varies from weeks to months or even a year or more at times. The disease begins as a tiny papule which enlarges to form a plaque of 2 or 3 or even 6 or 8 centimeters in diameter. The lesions usually soften and discharge a sticky material which dries and forms crusts, beneath which is an ulceration with a pink, edematous areola. At times the lesions do not break down and ulcerate. Eventually the crusts fall and are apt to be followed by scars which may be rather deforming. The lesions are situated often on the uncovered parts (face and extremities), rarely on the trunk, and never on the palms, soles or hairy scalp. They may be single or multiple. In rare cases there may be 100 or more lesions. The name Aleppo boil is a misnomer, as the disease has no resemblance to a furuncle.

The course of the disease is self limited and usually disappears within a year, as the Turkish name *habel-seneh*, or "button of one year," would indicate. The disease causes no constitutional and only slight subjective symptoms. It leaves no sequelae except scars and is usually followed by permanent immunity. Occasionally the disease lasts for years, and it may recur. In both chronic and recurring types a tuberculoid structure is found on microscopic examination. The histologic structure of the ordinary type is that of a granuloma without any characteristic features.

A positive diagnosis can be made with certainty only by finding the causative organisms in smear preparations or by culture. In cases such as the relapsing (tuberculoid) type it is usually impossible to demonstrate the organisms either by direct microscopic examination or by culture. Here intracutaneous tests by cultures of killed organisms may be of great assistance. Such tests are positive in a large proportion of cases. The clinical diagnosis may be difficult in endemic regions, but other diseases must be considered, including ecthyma, syphilis, tuberculosis, blastomycosis and tropical and other ulcers. A feature which aids in differentiating blastomycosis is the failure of the latter disease to respond to treatment by antimony and potassium tartrate.

In the treatment of oriental sore, innumerable remedies have been tried. When the lesions are extremely numerous it is advisable to use intravenous injections of antimony and potassium tartrate. For the ordinary case with one or two lesions, freezing with solid carbon dioxide is recommended. X-ray therapy gives good results, but this entails expensive apparatus as well as skill in its use. The so-called *grenz rays* have recently been used in Palestine with success in the treatment of the relapsing type, which has hitherto been resistant to all therapy. Prophylactic treatment con-

sists in personal hygiene and proper care of abrasions. To afford protection against the bites of the sandflies it is advisable to sleep under a net containing forty-five holes to the square inch and to use insect repellents by day. In endemic areas, infected persons should be treated and lesions should be covered by protective dressings.

AMERICAN LEISHMANIASIS

The mucocutaneous type (American leishmaniasis) is found in the Yucatan peninsula, in parts of Central America, especially Guatemala, and in every country of South America except Chile. The greatest number of cases is found in Brazil, followed in frequency by Peru, Bolivia and Paraguay.

The disease is seen chiefly in men as the result of their occupation as foresters, workers on tea plantations or collectors of chicle for chewing gum. American leishmaniasis occurs in moist tropical regions with luxuriant vegetation. One type of the disease, however, occurs on the slopes of the Andes at altitudes varying from 3,000 to 8,000 feet.

American leishmaniasis has more than the usual number of local names, no less than twenty-three different designations being given to it in South America. In Peru alone there are six local names, one of which, "espundia," has been improperly used in textbooks for a disease that occurs in all the Americas. No one ever employs this local name in Brazil, where the greatest incidence of the disease is found.

The most striking clinical difference from oriental sore is the presence of lesions of the nose and throat in 15 or 20 per cent of the cases. These lesions are sometimes responsible for severe mutilations of the nose and upper lip as well as of the pharynx. The lesions of the nose and throat are usually preceded by one to fifteen years by cutaneous ulcers, which are extremely sluggish and may last for years. They do not show the tendency to spontaneous healing of oriental sore. It is also questionable whether a permanent immunity follows healing in the American type of the disease. It is probable that some species of *Phlebotomus* serves as the vector. There is, however, no known animal reservoir corresponding to the dog, which is often infected with oriental sore.

Laboratory investigations suggest that *Leishmania tropica* and *Leishmania braziliensis* are different species and the causative organisms of oriental sore and American leishmaniasis respectively. Noguchi found that cultures of these organisms as well as of *Leishmania donovani* (kala-azar) agglutinated only cultures of their respective organisms and concluded that there were three separate species of *Leishmania*. His work was confirmed by Khgler but not by others. However, Geiman has lately observed cultural differences when using the chorioallantoic membrane of the chick embryo. Cultures of *Leishmania tropica* were produced in twenty-six passages, whereas *Leishmania braziliensis* lived only to the second passage. It has also been suggested that certain organisms growing in symbiosis with *Leishmania* may be responsible for the clinical differences in the two types of the disease. Seidelin found a gram positive diplococcus which in 2 cases at least was the only other associated organism and in 1 case the skin was unbroken.

The treatment of American leishmaniasis is less satisfactory than that of oriental sore. The cutaneous lesions yield to antimony and potassium tartrate and this

remedy may cure the lesions of the mucous membranes. It may fail to cure the latter lesions, and better results have been obtained in Brazil by using a French arsenical preparation known as "Épaiseno."

PINTA

The term *pinta* is derived from the Spanish word *pinta*, meaning a spot, and like many other tropical diseases, it has numerous local names. In Mexico it is called *mal del pinto* and in Colombia *carate*. These two countries show the greatest incidence of the disease, a careful survey in the southern half of the republic of Mexico having shown over 270,000 cases. The disease is also seen to a less extent in Venezuela, in Peru, in Ecuador, in some of the islands of the West Indies and in Central America.

Pinta is an infectious disease caused by a spirochete which is morphologically identical with the organisms causing syphilis and yaws. It has no relationship to fungi, as was erroneously stated in textbooks for forty years.

The first clue as to the true nature of the disease was the discovery by Menk in 1927 that 75 per cent of cases gave a positive Wassermann reaction. With improved technique this was later found by the Mexican commission to be close to 100 per cent in the pigmentary stage of the disease. The causative organism was discovered in August 1938 by Grau Triana and Armenteros working in the laboratory of Saenz in Havana. In the following year Leon y Blanco proved that the disease could be inoculated in man and that it frequently showed primary and secondary lesions of nondescript character which lasted for months or years. He also proved that the disease was inoculable in persons suffering from latent syphilis.

Previous to the past four years it was thought that the manifestations of *pinta* were confined solely to pigmentary changes in the skin. The most characteristic change in color in the pigmentary or late stage is a leaden or slaty blue which occurs in patches or freckles, especially on the exposed parts of the body. Favorite sites include bony prominences such as the forehead, nose, malar region, knuckles, knees and ankles. The eruption often shows a tendency to symmetry, though in rare instances it may involve only one side of the body (*hemipinto*). Blue patches may also affect the mucous membranes of the mouth. Eventually the blue color tends to disappear and may be followed at first by partially depigmented areas and later by completely depigmented ones simulating ordinary vitiligo.

Red *pinta* is the somewhat misleading term used for a rare type of eruption. It consists simply of a generalized, mild flushing of the skin similar to the appearance of a person after taking a hot bath. This type is associated with the ordinary blue pigmentation and depigmentation.

As *pinta* affects the dark races almost exclusively (Indians, Negroes and those of mixed blood), it is obvious that the vitiligo-like areas may be extremely disfiguring. This usually constitutes the only ill effect of the disease, as it apparently does not cause subjective symptoms and does not affect the general health.

There is no known vector of *pinta*, and it is most probable that the disease is transferred from one person to another by contact.

The course of the disease when untreated is extremely chronic, lasting often for decades. The early lesions

respond well to antisyphilitic treatment and the same is true of the blue areas in the late (dyschromic) stage. However, when the stage of complete depigmentation (vitiligo) is reached the change in the skin is permanent. *Pinta* leaves no sequelae except permanent depigmentation in untreated cases. It is not a serious disease except for the cosmetic defect, which at times is most disfiguring.

140 East Fifty-Fourth Street

TROPICAL LYMPHANGITIS AND ABSCESES

ARTHUR W. GRACE, M.D., D.T.M. AND H. (ENG.)

Professor of Dermatology and Syphilology, Long Island College of Medicine

BROOKLYN

During the period 1926-1928 I conducted an investigation in British Guiana, under theegis of the Tropical Diseases Committee of the Royal Society of London and the London School of Hygiene and Tropical Medicine, into the bacterial complications of filariasis. Studies were made of the frequency and sites of occurrence, distribution by age, race and sex, clinical manifestations and bacteriology of all cases of lymphangitis, abscess and elephantiasis admitted to the inpatient and outpatient departments of the Public Hospital, Georgetown, between June 1927 and September 1928, of the serologic relationship between strains of the beta hemolytic streptococcus isolated from cases of lymphangitis with abscess in British Guiana and the commonest strain of the same organism isolated from the throat in cases of scarlet fever in New York City, of the relationship between the cutaneous response to inoculations of toxin prepared from the British Guiana and New York streptococcus strains and the presence of *Microfilaria bancrofti* in the peripheral blood, of the relationship between the nature of the organism found in abscesses and the presence of *Microfilaria bancrofti* in the peripheral blood of the same individual, and of the relative distribution of *Microfilaria bancrofti* among the different races and age groups of Georgetown. The choice of British Guiana for the work was a fortunate one in that the population is chiefly composed of three races, among whom it has long been known that the manifestations of filariasis differ considerably in degree and in frequency of occurrence. The racial groups include East Indian, Negroes and Portuguese and Mixed, the latter term denoting individuals having both Negro and Portuguese blood. The results of the investigation were published as No. 3 of the Memoir Series of the London School of Hygiene and Tropical Medicine.¹ As the memoir is the only report yet published in which an attempt has been made to clarify the relation between the clinical entities of lymphangitis, abscess and elephantiasis on the one hand and the disease agents *Wuchereria bancrofti* and the beta hemolytic streptococcus on the other, much of the data of the present paper have necessarily been derived from it.

From the Long Island College Hospital and the Department of Dermatology and Syphilology, Long Island College of Medicine.
This paper is a symposium on "Tropical Diseases of the Skin," published under the auspices of the Section on Dermatology and Syphilology.

TROPICAL LYMPHANGITIS

The geographic distribution of tropical lymphangitis has not yet been accurately determined. In view of its undoubted close association with *Wuchereria bancrofti*, its presence should be suspected in areas where the parasite is endemic, namely in almost every tropical and subtropical country. The term "tropical lymphangitis" is restricted in this paper, and should always be restricted to those cases which arise without any detectable break in the skin of the segment of the body of which the lymphangitic area forms a part. Such lymphangitis is rare in temperate latitudes in which the inflammatory condition is almost invariably the sequel of trauma or much less frequently of dermatophytosis. The precipitating causes of tropical lymphangitis (hereafter referred to as lymphangitis), as construed by its sufferers, are manifold and include a sprain, a wrench or getting the feet unusually wet or cold, the great majority of attacks however, arise without any apparent cause. Lymphangitis is generally of sudden onset and affects the lower limb in about four fifths of all attacks, the other structures affected, in descending order of frequency, are the upper limbs, the breast and the scrotum. The distribution of attacks in the lower limbs is along the line of the great and small saphenous veins, where three areas are particularly involved namely the middle of the inner part of the thigh, the upper inner portion of the leg and, least frequently, the middle of the calf. In the upper limbs the disease is usually found along the inner aspect, the upper portion of the upper arm being rather more frequently attacked than the corresponding site of the forearm. In the breast and scrotum the upper outer quadrant and the most dependent part respectively, are the common sites of involvement. Lymphangitis is very largely a disease of young people. First attacks occur in almost 80 per cent of cases before the age of 30 and most frequently in the age group 10 to 19. If one also includes recurrences, only about 60 per cent of cases are found under the age of 30 years and the maximum number of attacks appear in the 20-29 age group. Both extremes of life may be attacked, the youngest patient was 18 months old and the oldest 74 years. There is sometimes a striking difference in the relative frequency with which lymphangitis occurs among different races living under approximately the same conditions, this applies particularly to the Portuguese and Mixed on the one hand, who suffer heavily, and the East Indians on the other in whom the disease is uncommon. Women are more frequently affected than men in the ratio of about 3 to 2.

The attack of lymphangitis is invariably of sudden onset and is ushered in with severe, deep-seated pain localized to a small area. In the recurrences, which are common, the pain usually begins in the same site as that originally affected. Within a few hours erythema has developed over the painful area and, together with the pain begins to spread the latter throughout the whole of the segment of limb or organ involved and the erythema in streaks along the lymphatics toward the adjacent nodes. The temperature now begins to rise, reaching a peak of 102-103 F in about six hours by which time the attack is at its height and the patient is prostrated. At this point the affected part is intensely painful, erythematous, tense and edematous, and lymphangitis is well defined. The satellite nodes are enlarged and tender but there is little erythema of the overlying

skin. At the end of twenty-four hours the temperature begins to fall, the signs and symptoms to abate and within the next two days the acute attack has passed off. Pain, however, remains in the part for another three or four days, after which the latter presents the same appearance as it did before the attack. It is impossible to predict when lymphangitis will recur, for there is no time relation between successive attacks. The period of remission may be measured in days, weeks, months or years or there may be only one attack in all. The description just given fits the common type of attack. Milder cases are found in which the involved area is no larger than the palm of the hand and the patient is so little inconvenienced that he can carry on his regular work, in others, however, the entire trunk and limbs may be intensely painful and erythematous and the constitutional symptoms of such severity as to endanger the life of the patient. Such severe attacks may last as long as seven or eight weeks. Lymphangitis is not associated either with desquamation of the skin, or vesicle or bulla formation, or with softening and fluctuation of the satellite nodes. In about 10 per cent of cases of lymphangitis, nodules appear in the center of the involved area. They are very hard, exquisitely tender, freely movable on the deeper tissues, and measure approximately 2 by 2 by 0.5 cm. They are attached to the overlying skin, which is erythematous and edematous but not elevated, and are wholly within the subcutaneous tissue. Over four fifths of the nodules subside without softening and disappear completely within a week, the remainder develop into an abscess which contains the beta hemolytic streptococcus in pure culture. In about 20 per cent of hospitalized cases of lymphangitis an abscess appears in the affected area. It requires about eleven days, with limits of three and twenty-one days, after the onset of an attack for such an abscess to be ready for evacuation, by that time the acuteness of the attack has subsided considerably. The exact proportion of persons who develop abscess in association with lymphangitis is not known, as the milder cases, which constitute the majority, not only are not seen in the hospital but are often successfully treated with home remedies.

Attacks of lymphangitis in limbs and organs which are elephantoid closely resemble in most aspects those in nonelephantoid tissues. There are, however, three differences. First, the elephantoid structure reacts as a whole with pain, erythema and edema, the localized areas of involvement so common in nonelephantoid tissues do not occur. Second the hard subcutaneous nodules are found only about one fourth as frequently in lymphangitic attacks in elephantoid as in nonelephantoid tissue. Third, the elephantoid limb is slightly more prone to the development of abscesses following in attack of lymphangitis than is its nonelephantoid counterpart.

Lymphangitis is one, but in British Guiana the least common, of the predisposing causes of elephantiasis, which most frequently arises about two years after the appearance of an abscess in the part which subsequently becomes elephantoid. There is indirect evidence to show that such abscesses are due to the beta hemolytic streptococcus, which is also by far the commonest organism producing infections of elephantoid structures, outnumbering its nearest rival the hemolytic streptococcus by 4 to 1.

ORGANISMS ASSOCIATED WITH LYPHANGITIS IN
LELLPHANTOID AND NONLELLPHANTOID TISSUE

Material for this study is best obtained during an attack of lymphangitis by culture of blood, of material aspirated from nodes and subcutaneous tissues and of pus from abscesses. I found positive blood cultures in approximately 10 per cent and Rose² found positive node punctures in almost 90 per cent of persons hospitalized with acute lymphangitis. The sole organism found in the cultures was the beta hemolytic streptococcus which was also present in pure culture in 25 of 27 abscesses which followed acute lymphangitis. There are no statistics on the frequency of recovery of bacteria by aspiration of inflamed subcutaneous tissues.

The close association of the beta hemolytic streptococcus and lymphangitis and the rarity of such lesions in temperate climates raises the question of the existence of a type of the organism peculiar to lymphangitis or to British Guiana. An answer to this query was sought by studying the fermentation reactions, morphology, serologic reactions, virulence and skin reaction to toxins of the British Guiana beta hemolytic streptococci in comparison with those of beta hemolytic streptococcus strains commonly found in New York. The results of the study were as follows:

Fermentation Reactions.—Of 68 British Guiana strains, 61 fell into the pyogenes, 5 into the subacidus and one each into the anginosus and equi groups.

Morphology.—Sixty-one British Guiana strains, when streaked on 5 per cent horse blood veal agar and examined microscopically, fell into three morphologic types, I, IIa and IIb, which could be readily identified by tint, periphery and granularity of the colony. Type I constituted 14.8 per cent and was light in color, had a noncrenated periphery and was free, or almost free, from granularity. Seventy-two and one-tenth per cent fell into type IIa and were dark with a finely crenated periphery and well defined granularity. Thirteen and one-tenth per cent belonged to type IIb and were much darker and much more coarsely granular than those of type IIa, the periphery was only roughly circular owing to the coarseness of the crenations. All of the type IIb strains belonged to the subacidus group. No mucoid strains were observed.

Serologic Relations.—The criterion of identity of strains was reciprocal absorption of agglutinins. A stable homogeneous suspension of organisms for agglutination tests was made by repeated subcultures in phosphate glucose broth. Six British Guiana pyogenes strains isolated from abscesses in as many individuals during an attack of lymphangitis were studied serologically. Only one dissociated into fine and coarse variants during subculture, it is the fine variant which is considered here. Five of the six strains were identical but there was no reciprocal absorption between them and a common scarlet fever strain from New York. Eight British Guiana subacidus strains, all belonging to type IIb, were serologically identical with one another and different from subacidus strains obtained from London and New York.

Virulence.—There was practically no increase in the virulence, originally low, of strains of type I and type IIa after passage through mice. The virulence of the very coarse type IIb strain was so low that 10 cc. of a twenty-four hour broth culture failed to kill mice.

Skin Reaction to Toxins.—Toxin prepared from three British Guiana strains was employed in almost three hundred tests in conjunction with that derived from a scarlet fever strain, there was a high degree of correlation between the results obtained with all the strains.

Neutralization of Toxin by Antiserum.—Toxin prepared from a British Guiana strain associated with lymphangitis was not neutralized by antistreptococcus serum derived from a scarlet fever strain. No toxin demonstrable by intradermal tests on Dick positive children was produced by the very coarse type IIb strains.

It would appear, then, that the hemolytic streptococcus of British Guiana has the following chief characteristics. The texture of the colony is principally granular, a common agglutinogen was found among a number of strains obtained from cases of lymphangitis, there was absence of serologic relation with a common scarlet fever strain, a serologically unique subacidus group exists, virulence for mice is low, there is no production of toxin by strains of very coarse colony texture, toxin produced by nongranular strains is not neutralized by antiserum derived from scarlet fever streptococci, approximately 90 per cent fall into the pyogenes group, and a toxin similar in its intradermal effect to that derived from a common scarlet fever strain is produced. It is evident, then, that there is some degree of difference between the beta hemolytic streptococcus of British Guiana and that of temperate climates.

ABSCESSSES

The frequency and site of occurrence of abscesses varies considerably in different tropical countries. Thus the annual incidence of abscesses per unit of population is over eight times, and the proportion of lower limb abscesses over four times, as high in British Guiana as in Jamaica.³ It is most likely that this difference is related to the less common use of footwear and the lower standard of living in British Guiana, where approximately 350 abscesses are opened annually in the Public Hospital in Georgetown, a city of 53,000 inhabitants. In over three fourths of the cases there is no visible lesion to account for the development of the abscess. Staphylococci are responsible for 53 per cent and the beta hemolytic streptococcus for 33 per cent, and about 12 per cent are bacteriologically sterile. These ratios apply not only to the population of the colony as a whole but also, with only slight divergence, to each of the three races in British Guiana, namely the Negro, the East Indian and the Portuguese and Mixed. Infection occurs in the lower limbs twice as frequently as in the upper limbs and four times as often as in the chest wall and abdominal wall. While all ages are subject to the development of abscesses, the maximum incidence is found in the third decade. The proportion of infection due to the staphylococcus is highest in the first decade and declines with increasing years, whereas the reverse is true for the streptococcus. Males are affected more frequently than females in the ratio of five to three. As has been pointed out, the staphylococcus is not rarely responsible for attacks of lymphangitis. Not only infections with the beta hemolytic streptococcus, however, in endemic filarial countries are associated with lymphangitis—in fact, only about one fifth are associated. It is impossible, therefore, to predict the nature

³ Grace A. W., Grace F. B. and Warren S. The Incidence of Filaria Bancrofti and the Beta Hemolytic Streptococcus in Certain Tropical Countries. *Am. J. Trop. Med.* 12: 433 (Nov.) 1913.

² Rose, F. G., quoted in reference 1.

of the organism in an abscess unassociated with lymphangitis, a rough guide is sometimes obtained from its location, the staphylococcus being predominant in infections above the shoulder and the streptococcus in the scrotum. Abscesses occur in the subcutaneous tissues and in the muscles, both superficial, as in the recti abdominis, and deep, as in the inner aspect of the quadriceps femoris. An intramuscular abscess may contain either the staphylococcus or the streptococcus. The staphylococcus has a tendency to produce multiple abscesses, often at widely separated sites which are prone to recur. Specimens of pus from staphylococcal and streptococcal abscesses are, in most instances, identical in appearance. Deep, long standing, intramuscular streptococcal abscesses, however, contain pus which is characteristic in that it is very fluid and of a dirty brown tint, probably from altered blood. Such abscesses are usually the result of an attack of lymphangitis, occurring three weeks to a month previously, in an elephantoid leg. The patient is often unaware of the existence of the abscess, which may contain as much as a pint of pus.

THE RELATION OF WUCHERERIA BANCROFTI TO LYMPHANGITIS

It was concluded in the Memoir¹ that "it is possible that lymphangitis and elephantiasis do not occur in a race or age group or country to any extent in the absence of *Filaria bancrofti*, and that the exciting cause of practically all the attacks is the beta hemolytic streptococcus, which may itself be of a particular type." It will be noted from the chart not only that the incidence of beta hemolytic streptococcus abscesses, the percentage of individuals showing *Microfilaria bancrofti* in the blood and the incidence of lymphangitis and elephantiasis are all low in the first decade of life but also that they all rise rapidly in the next decade. It is impossible to avoid the conclusion that there is a relation between these entities.

Sufficient evidence has been advanced in this paper to show the connection between lymphangitis and the beta hemolytic streptococcus. What part does *Wuchereria bancrofti* play in the picture? It seems certain that it does not of itself produce lymphangitis.⁴ Any theory of the causation of lymphangitis, however, which omits the worm as a factor must perforce, ascribe the condition to the beta hemolytic streptococcus alone. As that organism is widely distributed in temperate climates, where tropical lymphangitis is a rarity, it would be necessary to prove, in support of this theory, that the beta hemolytic streptococcus of lymphangitis is of a vastly different character from that of temperate climates. The differences between the organisms from tropical and temperate latitudes have already been stated and are, in my opinion, insufficient to warrant the designation of the beta hemolytic streptococcus as the sole factor in the production of lymphangitis. I believe that the sequence of events leading to an attack of lymphangitis is as follows. There is some degree of obstruction to the flow of lymph owing to the presence of the adult worm in the lymph nodes and channels. The existence of lymph stasis renders the tissues more susceptible to infection by the beta hemolytic streptococcus. Once infection has occurred the tissues of the affected

area become hypersensitive to the beta hemolytic streptococcus and its products and attacks of lymphangitis may be occasioned by organismal or toxic stimuli of intensity too low to be appreciated by tissues previously uninvolved. Evidence in support of this hypothesis is twofold and indirect. First, Drinker⁵ has shown that the lymphedematous leg of a dog is not only susceptible to spontaneous infection with hemolytic streptococci but could be infected very readily by injection of hemolytic streptococci. Second, the East Indian has the lowest microfilarial rate and also the lowest incidence of lymphangitis and elephantiasis of the three chief races in British Guiana, that the infrequent occurrence of these clinical entities is not due to a relative insusceptibility to the beta hemolytic streptococcus is shown by the fact that streptococcal abscesses occur just as commonly in the East Indian as in the Negro and in the Portuguese and Mixed.

Incidence at different ages of abscesses due to staphylococci abscesses due to beta hemolytic streptococci first attacks of lymphangitis onset of elephantiasis and *Microfilaria bancrofti* in blood

By what means does the presence of *Wuchereria bancrofti* render the tissues more susceptible to infection with the beta hemolytic streptococcus? An unsuccessful attempt was made to answer this question by subjecting 52 individuals, whose night blood had previously been examined, to skin tests with scarlet fever and British Guiana streptococcus strains, and also by studying the night blood of 300 persons with abscesses the bacterial nature of each of which was known. No relation was found between the presence of microfilaria in the blood and either a positive reaction to streptococcus toxin or the existence of the staphylococcus or streptococcus in abscesses.

⁴ Croll quoted in reference 1

⁵ Drinker C K and Yaffe J H. Lymphatic Lymph and Lymphoid Tissue. Cambridge: Harvard University Press, 1941.

TREATMENT AND PROPHYLAXIS

Prior to the introduction of the sulfonamide drugs, treatment of lymphangitis consisted in rest, local application of heat and acetylsalicylic acid. Vaccines prepared from local strains of the beta hemolytic streptococcus were felt to be of value in reducing the frequency of recurrences. At present the most efficacious remedy is either sulfathiazole or sulfadiazine in doses of 1.5 Gm. three times daily for one week. Abscesses should be incised and drained. No means exist for destroying or removing the adult worms of microfilariae. As *Wuchereria bancrofti* is transmitted by the bite of the female *Culex fatigans*, antimosquito measures will help to reduce the incidence of the disease.

LEPROSY

EPIDEMIOLOGY AND NATURAL HISTORY

CHESTER N. FRAZIER, M.D.

CAMERON, TEXAS

It may be said without risk of serious contradiction that less is known of the essential factors in the pathogenesis and transmission of leprosy than of the other great infectious diseases of mankind. This defect in our knowledge stands out more prominently when one remembers that leprosy has held the attention of countless persons over centuries of time and has been recognized by layman and physician alike as one of the major scourges of the human race. It is a noteworthy historical fact, in this connection, that leprosy was among the first, if not the first disease the cause of which was ascribed to a bacterial organism. Hansen first reported the finding of a bacillus as the possible causative agent of leprosy in 1874. It was not until 1882 that Koch announced the identity of the bacillus of tuberculosis.

The faltering progress of our knowledge is to be attributed in part at least to the remoteness of the great endemic foci of leprosy from the centers of scientific investigation and to the barriers raised against its study by the unique emotional qualities which have characterized the attitude of man toward those afflicted with the disease. Persecution and social ostracization have been the fate of the leprous person. The almshouse and the asylum have been his refuge rather than the hospital from which he could look forward to rehabilitation through an objective approach to the solution of his problems. Even today there are rumors of the massacre of its victims.

But, in spite of these accidents of geography and human behavior, many serious attempts have been made to understand the nature of the infection. Most of these, however, have ended in failure. There is yet no certainty that the Hansen bacillus has ever been cultivated on artificial mediums nor has the disease in progressive form been established in laboratory animals. Direct transmission to human subjects by inoculation of infectious material has also failed. Without these achievements, scientific inquiry is handicapped and the position of *Mycobacterium leprae* as the cause of the disease remains unsettled.

From the Department of Dermatology and Syphilology, University of Texas Medical School.

This paper, in a symposium on "Tropical Diseases of the Skin," is published under the auspices of the Section on Dermatology and Syphilology.

Furthermore, there is a lack of understanding of the natural history of leprosy, without which there can be no sound judgment of the effects of therapeutic measures. Interpretation of the manifestations of infection is confused and complicated too frequently by our engrossment in the naming of the types of disease and the forms of lesion, a practice which too often tends to obscure rather than enlighten our understanding. An almost total absence of any accurate quantitative knowledge of the incidence of infection, and of the rate at which it attacks various groups in the population prevents a scientific evaluation of the effects of regulatory control.

But, regardless of the many shortcomings in our knowledge and the absence of a rational plan of prevention, leprosy has been on the decline as an important force of morbidity in Europe and the British Isles since the thirteenth century, when it reached its zenith in that part of the world.¹ In Asia it would seem that the rate of infection now remains stationary, but this is only an impression.

It has been predicted that the disease will disappear through the application of sound principles of public health technique. This undoubtedly oversimplifies the explanation of the gradual decline of the infection. But, as Muir² has stated, "Whatever the actual causes which control the spread of leprosy, it seems clear that it belongs to a certain stage of human social development." It is not found among nomadic and aboriginal peoples until they forsake their tribal customs and merge with and adopt the life and practices of more civilized people. But as their state of civilization advances with its attending improvements in personal hygiene, nutrition and sanitation the decline of the disease becomes apparent.

Leprosy, then, may be taken as a good example of the effect of social and economic forces in the production of disease. This aspect of the problem requires more careful consideration in the epidemiologic study of the infection. To give it such might aid in shedding light on the reasons for the localization of the disease in certain communities and assist in explaining on grounds other than heredity the apparently higher rate of attack among certain racial elements, frequently foreign born. As another has written, leprosy is a "disease of the crowded house, room and bed." It may well be that the observations of Jonathan Hutchinson³ who attributed the disease to the consumption of tainted fish, have in them the essence of truth. It is not so much the eating of spoiled fish but the necessity of so doing that should claim our attention.

LEPROSY IN THE UNITED STATES

Today leprosy as a serious problem of public health is limited chiefly to the tropics and subtropics. The great foci of disease are in central Africa, in India and in parts of China, with smaller endemic areas in Central and South America and in Mexico. As a problem in this country leprosy is only of minor significance. There are but few endemic centers in which it seems the infection can be transmitted. These are confined to three of the states bordering the Gulf of Mexico, namely, Louisiana, Texas and Florida. Other localities with

New York City, in which the leprosy are always to be found, are not areas of infectivity "With a single exception," in the words of McCoy⁴ of the Public Health Service, "I have been unable to find any record that any one has ever been infected with leprosy in New York City, although in the aggregate over a period of a few decades literally hundreds of lepers have been domiciled there for varying periods of time."

The oldest focus of infectivity in Texas is in Galveston. This was made the subject of an epidemiologic report by Boyd and Fox⁵ in 1920. No important conclusions were drawn from this investigation, but it is of interest to note in view of the attempts to relate the human infection to the murine type of leprosy, that from an examination of some 23,000 rats for the plague in this locality only 7 leprosy rats were identified by the detection of acid fast bacilli in smears from their tissues.

MURINE LEPROSY

In 1903 Stefansky,⁶ working in Odessa, observed a leprosy-like disease in rats. Almost at the same time, and independently, Dean⁷ in England described the same disease. In certain anatomic manifestations, and in the presence of acid fast bacteria, the disease of the rat resembles human leprosy. The organism of murine leprosy *Mycobacterium leprae murium*, has been regarded by some⁸ as perhaps identical with the organism of human leprosy, *Mycobacterium leprae*. But there is no convincing evidence to support this assumption. It may possibly be, however, that studies of this organism in the future will shed light on the relationship of the acid fast mycobacterium to human leprosy and help elucidate some of the problems related to the disease.

In this connection I wish to refer to a study of the epidemiology of leprosy in Australia by Cook,⁹ who reported that the disease showed a distribution like that of the rat flea *Xenopsylla cheopis*. He raised the question of an insect vector with the rat serving as the reservoir of infection, the assumption being that the organisms of murine and human leprosy were identical.

TRANSMISSION OF INFECTION

The communicability of leprosy has been acknowledged since Biblical times. However, this view was discredited temporarily by Danielssen and Boeck when they introduced the concept of hereditary transmission. In Norway the focus of the disease failed to disappear, as had similar foci in other parts of Europe. These observers saw that the disease tended to be confined to certain families. Their remarkable publication on leprosy, "Om Spedalskhed" remains one of the classic landmarks in the history of the disease.¹⁰ The part hereditary influences may have in affecting the susceptibility of the individual to leprosy still holds the attention of some investigators.¹¹

I mention this departure from the accepted theory of transmission to direct attention to the familial nature of the disease and the problem of household contact. I have already referred to the need of quantitative data on the rate of transmission of infection as a necessary prelude to the scientific study of the results of control and call attention here to the important work of Doull,¹² who studied the attack rates of leprosy within the family group. Thus he did in retrospect, using material from the Philippine Islands, by applying the principles of the life table to the measurement of the risk of attack.

HOUSEHOLD ATTACK RATES

For all ages, Doull found the annual risk of contracting leprosy was about five times as high among those having household exposure as among the group who were not subjected to this risk. The attack rates for those exposed were better demonstrated by cumulating the rates to the age of 20 years. Assuming that there was no selective mortality among the leprosy, it was found that 170 per thousand of family contacts could be expected to show evidence of the disease. For those not in household risk, the comparable figure was 30 per thousand.

Evidence showing the higher susceptibility of those in early life was also obtained from this study. The ratio of the attack rate for the age group 10 to 14 years to the rate for the group 20 to 29 years was 5.1 to 1 and, for the nonexposed, 2.8 to 1.

The results of Doull's analysis support the commonly accepted view of the infectivity of the disease on close and prolonged contact. Further application of the same statistical technique to the measurement of infectivity under varying circumstances is desirable.

DISTRIBUTION OF LEPROSY IN CHINA

The wide distribution of leprosy throughout the world has raised questions as to the geographic influences on the transmission of infection. Rogers,¹³ from a study of the disease, especially in India, reached the conclusion that the only factor of this nature common to the scattered endemic foci was a state of high atmospheric humidity.

The vagaries of the geographic distribution of leprosy are well illustrated by a study of the location of endemic areas in China. Over a period of twenty years, while a member of the staff of the Peiping Union Medical College, I was interested in this aspect of the disease. Unfortunately the data on the subject are now beyond my reach, but it may be stated that during all that time, with a single exception, no case of leprosy was observed which had been contracted definitely in Hopei province, of which Peiping is the capital. The only patient who had resided continuously in Hopei came from a small village in the southern part of the province near the Shantung border. In Shantung there is a large endemic focus of leprosy.

While the number of leprosy patients seen annually in the hospital in Peiping was not large, it must have been true that the city had harbored the disease for many years, perhaps centuries, a time sufficient to have allowed the establishment of an endemic focus had the environmental conditions been congenial to the transmission of the disease.

Peiping lies in the great North China plain. For the greater part of the year, except in early and middle summer when the rains come, the climate is very dry and the skies are cloudless. The winters are cold and the summers hot. The city is situated approximately at 40 degrees north latitude. Following this parallel to the west there is apparently no leprosy in the adjacent province of Shansi, but proceeding to the extreme western part of the country toward the highlands in the province of Kansu the disease is endemic. There are large areas of infectivity in the Yangtze valley, especially in the region of the city of Hankow and in the southern province of Kwangtung.

Before the onset of hostilities in 1937, and prior to the subsequent migration of great masses of the population, there existed in China favorable conditions for the epidemiologic study of leprosy. The unique place of the family in the social organization with the close association of its members including not infrequently two and three generations under the same roof, the widely scattered endemic areas embracing extremes of climate and topography and the accompanying ethnologic and demographic variations in China's population offer rich opportunities for investigation. As it is, the only record of the pattern of distribution in the country is a general survey made through the medium of questionnaires by Fowler¹⁴ which should be read by those interested in the subject.

NATURAL HISTORY OF LEPROSY

There is little need at this time to enter into a description of the clinical phenomena of leprosy. However, it is pertinent to the discussion to emphasize the need for a clearer and fuller understanding of the natural history of the disease. Too frequently we are influenced by the formalized and static picture given in the books. Leprosy is a disease of great chronicity and as such it is subject to a wide variety of changing clinical sequences. To divide the disease into carefully defined categories, as for example nodular and anesthetic, is to miss the point of its evolution.

For the most part, if one will only observe the patient long enough and carefully enough there will be found periods of acute reaction alternating with periods when the infection is quiescent. The change in tempo is sometimes critical and profound. Periods of inactivity may persist for months or even years, when some force, usually not identifiable, appears to precipitate a relapse and further the progress of the disease.

Relapses are characterized by signs of acute reaction. There is evidence of redissemination of the infective agent. The cutaneous lesions may be exanthematous in form and distribution. Some may remain after the eruption as a whole has subsided to establish new foci of chronic inflammation. Areas of anesthesia may increase in size, and new disturbances in sensibility are usually to be detected at the site of fresh inflammatory lesions. The phenomenon of dissociation of the elements of sensation under such circumstances is noteworthy. The sense of temperature is lost first, followed as a rule by the loss, in succession, of the perception of pain and touch. Last of all, and rarely, is the loss of the sense of pressure. Nerve trunks may thicken and lymph nodes enlarge. Areas of skin, sometimes involving the entire face or a buttock, may acquire a swollen erysipelatous appearance.

ERUPTIVE LESIONS

As in syphilis, a great variety of eruptive lesions, both acute and chronic, may be found. The individual pattern of their form and distribution may vary considerably from patient to patient. This depends, no doubt, on the allergic capacity of the skin under varying circumstances. Chronic granulomatous lesions, not unlike those of tuberculosis in plaques and configurations, may develop.¹⁵ In these the histologic picture is that of typical tubercle formation. In fact the most typical tubercles of the skin are found not in tuberculosis but in leprosy.

Acid fast bacilli may, or may not, be found in the granulomatous lesions. Their absence in such cases need not cause surprise. Failure to find them by staining methods does not mean their absence in the tissue. In tuberculosis of the skin one almost never is able to demonstrate in fixed tissue specimens by staining methods the presence of acid fast bacilli. But almost always in such cases tuberculosis can be produced in susceptible animals by inoculation with portions of the material found to be free of organisms by microscopic examination.

The ease with which acid fast organisms can be demonstrated depends on the stage of inflammation when the search is made and on the method of examination. Fixed tissue preparations of skin and lymph node are best for this purpose.¹⁶ Very early and late in the course of the dermatitis the organisms are difficult, if not impossible, to find. In the latent case careful searching of many sections may not reveal a single acid fast form. Yet in a month's time they may be found in profusion should the patient develop an acute relapse.

TREATMENT

The value of the derivatives of hydnocarpus oil in the treatment of leprosy is difficult to define. Failure to take into account the rhythmic course of the infection, with its periods of alternating activity and latency, has led not infrequently to erroneous judgment of the efficacy of the drugs. From the experience in Peiping I am left wholly unconvinced that they serve any useful purpose. At times, when during the course of their administration acute relapse ensued, it was only reasonable to suspect that the hydnocarpace were in some way responsible. These reactions would occur occasionally even when small and carefully regulated doses of the drug were given. Whether because of the drug, I do not know.

For the present, it seems to me, a regulated way of living, with rest and nutritious food, and protection from injury, outside an endemic focus of infectivity, offers the patient the best chance of recovery.

No inflexible regulations for the quarantine of persons afflicted with leprosy need be set. In those places where the disease shows itself to be endemically infective, segregation may be practiced if it does not punish the patient. To punish him is to defeat in the end the purpose of quarantine. The leprosy person does not as a rule require asylum nor an almshouse, but does need hospitalization with the purpose always in mind of returning him to a life of usefulness and of respect.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS MCCARTHY, OBERMAYER, FOX,
GRACE AND FRAZIER

DR GEORGE M LEWIS, New York A year's experience examining men who have returned from the tropics has convinced McCarthy that the bulk of the superficial fungous infections to which the troops are subject are the same as seen in the United States, but in an exaggerated form. Secondary bacterial pyogenic superinfection is a more common complication than in civilian dermatologic practice in the United States. This may be due chiefly to factors inherent in a tropical climate and may be influenced by conditions of combat service. The tendency to latency and consequent neglect of *Trichophyton* gypseum infections and resistance to treatment of *Trichophyton purpureum* infections, both of which are of common occurrence in the United States, suggest that the infection may not always be newly acquired in the tropics. From what is known and from what McCarthy says, the treatment of all known fungous infections and the institution of prophylaxis is desirable. To be an effective prophylactic, a remedy may be easily usable, readily available, relatively nonirritating and yet mildly fungicidal. Talc reinforced by 0.5 per cent salicylic acid and the same concentration of thymol fulfils these conditions and also tends to counteract perspiration. When applied under and between the toes once or twice daily, the danger of acquiring a new infection is greatly lessened. The same remedy may be useful in treating mild fungous infections of the feet. All evidence points to the effect being due to a simple screening of the sun's rays by the lesions (Lewis, G M, and Hopper, Mary E. *Pseudoachromia of Tinea Versicolor*, *Arch Dermat & Syph* 34 850 [Nov.] 1936). When peeling of the skin occurs there is then manifest a contrast between the unchanged skin under the patch of tinea versicolor and the surrounding sun tanned skin. Treatment with 10 per cent solution of sodium thiosulfate continued for one to two weeks before exposure to the sun's rays will prevent the development of these apparently depigmented areas. Two statements of McCarthy regarding *T. purpureum* (rubrum) are at variance with my experience. If a suitable medium (using dextrose) is inoculated with *T. purpureum*, a red-purple pigment is invariably produced in the substrate (Lewis, G M and Hopper, Mary E. *Pigment Production by Fungi* 1 Nutritive Requirements, *ibid* 44 453 [Sept.] 1941). Because of this constant and primary characteristic, the laboratory recognition of the fungus is facilitated. At least 5 instances of follicular infection to *T. purpureum* have been recorded. The fungus may be considered an ectothrix, *Trichophyton* and not an *Endodermophyton*, as McCarthy states.

DR LEE MCCARTHY, Washington, D C I wish to thank Dr Lewis for his painstaking discussion of my portion of the symposium. I agree with him that the problem of the control of mycotic infections at the end of the war will have to be largely in the hands of the general medical practitioner and it is with this end in view that the present symposium was prepared.

COL J E ASH, M C, U S Army Little of the material and data that have come to the Army Medical Museum from our theaters of operation are as yet available for publication, but several years' experience in the tropics furnish some items that might be added to Dr Obermayer's list. I should like to emphasize the possibilities that can arise from chigoe bites. Indolent refractory ulcerations that may be 8 to 10 cm in diameter, and at times gangrene especially of the toes may result. It is also necessary to stress the frequency and persistence of the nonspecific ulcers of the skin that may result from any insect bites and from scratching, as well as from incidental trivial trauma. These lesions are usually pyogenic but they may be granulomatous. They are particularly common in children. A not too serious but very painful and fairly common lesion seen in some of our foreign possessions is produced by the larva of *Dermatobia hominis*. A favorite site for the female of the species to lay her eggs is on the exposed limbs but the head and neck may be involved. It is a spectacular boil-like lesion with a fairly large opening through which the larva protrudes and retracts its attenuated caudal end. The

larva is a flask shaped affair and cannot be extracted intact through the skin orifice. Surgical excision of the whole lesion is the treatment of preference. It is fairly common in Central and South America. Mention should also be made of *Larva migrans* (bot fly). Two of the *Arachnidae* might be added to the list: scorpion and tarantula. They give very painful bites which can lead to constitutional symptoms. The centipede—not the small soft thousand legger of the temperate zones but the formidable armored *Scolopendra* that may reach the length of 12 inches—can make a surprisingly large gash by a sweeping motion with its two vicious anterior claws. Serious local necrotic lesions and alarming general symptoms may result from the poison that he injects into the wound. Finally, the series of "stinging caterpillars" are something of a problem in Japan. There are several species: *Parasa hilarata*, *Miresa morata*, *Nygma* sp and others. The slightest contact with these larvae causes extensive, intense irritation and there are severe constitutional symptoms that may last for several days. The reaction is much more severe than that from our own brown tail moth. The museum is indebted to Dr R G Mills for the information and material on this subject that he deposited here some years ago.

DR M E OBERMAYER, Los Angeles Creeping eruption (*larva migrans*) should be included in a consideration of diseases of entomologic interest. However, since the disorder is more frequently caused by nematode larvae than by the migrant larvae of flies and since diseases caused by vermes do not form a part of this paper, creeping eruption was not included.

DR MORRIS MOORE, St Louis The importance of tropical diseases in our present crisis cannot be overemphasized in view of the various widespread theaters of war. Dr Fox has thoroughly covered, in a short space, the important features of yaws, cutaneous leishmaniasis and pinta. There remain, therefore, only incidental remarks which I would like to extract from my own acquaintance with these diseases and inject them into a discussion of the paper. Yaws, or frambesia, may be confused with several diseases. The frambesia form, usually considered to be the secondary stage, following the incubation period, may simulate a form of paracoccidioidid granuloma caused by *Paracoccidioides brasiliensis*. The type which localizes at the junction of the skin and mucous membranes and which resembles syphilitic condylomas may mimic the buccal mucosa type of paracoccidioidid granuloma caused by *Paracoccidioides cerebriformis*. Gangosa may be mistaken for tertiary syphilis. Mutilating leprosy must also be ruled out as well as American cutaneous leishmaniasis. Various workers have observed that the well advanced form of yaws closely resembles syphilis. However, as Stitt points out, in yaws the chief diagnostic point histologically is the pronounced involvement of the epidermis and slight change in the corium. Cutaneous leishmaniasis, an important tropical disease, may be transferred to the temperate zone. Dwork (K G *Arch Dermat & Syph* 45 676 [April] 1942) surveyed the literature of the United States and Canada and listed 24 cases in addition to 4 that he reported. All cases were of Near Eastern origin. The mucocutaneous type (American leishmaniasis), generally considered to be a New World disease, may occur in the Old World. Panja (G J *Indian M A* 7 2 [March] 1938) published the report of a case showing nodular lesions on the tongue. He also cites Napier and Das Gupta, who reported cases in which there were lesions on the mucous membranes of the hard palate, cheek and lips. In South America cutaneous leishmaniasis may easily be confused with paracoccidioidid granuloma, both the cutaneous and the localized buccal mucosa type. Occasionally the two diseases may be found in the same patient and this presents a problem in diagnosis. In addition to the diseases mentioned by Dr Fox, one should consider leprosy, rhinoscleroma and neoplasms. In examining sections of lesions histoplasmosis should be considered. In both diseases there is a proliferation of endothelial phagocytes which engulf the parasites. Leishmania and Histoplasma bear a striking resemblance and may easily be confused. Morza and the Bassos (*Vision de Estudios de Patologia Regional Argentina Univ de Buenos Aires* 1942 Pub No 63) found in the first stage of Chagas disease parasites which were leishmaniform in appearance. Pinta mal de pinto or caratu a la

World disease has recently been brought up to date by Pardo-Castello and Ferrer (*Arch Dermat & Syph* 45 843 [May] 1942). The disease manifests itself first as a papule (initial lesion), which becomes an oval or rounded patch. Other papules or macules form and merge to go into a second or disseminate stage. The disseminate form shows large plaques, termed pintids by Leon y Blanco, which may be syphilitic, lichenoid psoriasisiform, trichophytoid or eczematoid in appearance. The lesions show pigmentary changes of pink red, purple, slate color or brown. After a course of several months the disease progresses into the late chronic stage, presenting areas of hyperpigmentation and achromia. Finally there develop vitiligo. Aortic and cerebrospinal changes have been noted. The spirochete of pinta can be demonstrated among the epidermal cells, especially in the stratum malpighii. Pinta is known to occur in Peru in endemic foci.

Dr. HOWARD LON, New York. Dr. Moore is correct in saying that yaws may be confused with a form of paracoccidiodid granuloma (South American blastomycosis). In this case help could be obtained by the serologic reaction which in the early (secondary) stage of yaws gives close to 100 per cent positive reactions. Gangosa as Dr. Moore says, may be mistaken for tertiary syphilis. In my opinion gangosa is not a separate disease but merely a destructive sequel of another disease, which is usually yaws. It is possible, however, that the same destructive changes called gangosa may occasionally represent a terminal stage of syphilis. I agree entirely that the tertiary destructive form of yaws 'closely resembles yaws'. In fact it cannot be differentiated clinically. The purely cutaneous type of leishmaniasis (oriental sore) is a disease of the Old World. As far as I am aware, no autochthonous cases have appeared in the Western Hemisphere. The mucocutaneous type (American leishmaniasis) is confined almost entirely to the Americas, especially South America. It is true, as Dr. Moore has said, that the mucocutaneous type may be confused with South American blastomycosis. If the differentiation cannot be made by finding the respective organisms or by intradermal test, the therapeutic test with antimony and potassium tartrate may settle the diagnosis, as blastomycosis is not affected by this drug. With regard to the color changes in the dyschromic stage of pinta, on rare occasions a pinkish color may be present. This does not merit the appellation of redness, as a bright red such as scarlet or crimson is never seen in this disease. The dyschromic or pigmentary stage may appear a few months after infection with pinta, but such changes are more apt to appear after many months or even years later. Dr. Moore states that pinta is known to occur in Peru in endemic form. The disease is also endemic in many countries of Central and South America, as well as the West Indies.

Dr. GEORGE CHEEVER SHATTUCK, Boston. Dr. Grace says that the term tropical lymphangitis should always be restricted to "cases which arise without any detectable break in the skin of the segment of the body of which the lymphangitic area forms a part". In this presentation of his observations on inflammatory processes in the tropics, Dr. Grace has restricted his remarks to the category of cases thus defined. He says that cases belonging to this category are rare in temperate latitudes. I question whether in connection with lymphangitis associated with elephantiasis the differentiation of Dr. Grace is useful. Is it a fact that lymphangitis in nontropical cases of elephantiasis can usually be traced to an infection which has gained access to the body by way of a locally related lesion? I do not know the answer. His observation that abscesses are more than four times as common in British Guiana, where bancroftian filariasis is very common, as in Jamaica, where it is infrequent, points to a relationship between abscess and the filaria. This view is strengthened by the fact that fragments of an adult *Filaria bancrofti* have been found in a few instances in abscesses by Manson-Bahr and others. Dr. Grace's data suggest also that the beta-hemolytic streptococcus is of importance in the great majority of such abscesses. Perhaps the presence of the filaria in the tissues lowers local resistance to infection and prepares the way for the streptococcus. This was the opinion of John Anderson, who studied filariasis in British Guiana in 1921 (Filariasis in British Guiana. Clinical,

Pathological and Therapeutic Investigations, Research Memoir Series, London School of Tropical Medicine, vol. 5, memoir 7). We do not know accurately the geographic distribution of lymphangitis in the tropics in general. Neither do we know much about the local incidence of lymphangitis in the wider sense or of abscess. Such information is needed before sweeping correlations and comparisons can be made. Another interesting fact emphasized by Dr. Grace is that, of the three principal races in British Guiana, the East Indian has the lowest microfilarial rate and also the lowest incidence of lymphangitis and elephantiasis. That the East Indian is not less susceptible to infection with the beta-hemolytic streptococcus is shown by the fact that streptococcal abscesses are as common among them as among the Negroes, the Portuguese or the mixed elements of the population. Has the East Indian a high resistance to *Filaria bancrofti*?

Dr. ARTHUR W. GRACE, Brooklyn. The papers in the symposium have dealt with the common dermatologic entities of the tropics which are caused by fungi, protozoa, bacteria and tiny animal parasites. In our knowledge of these diseases there are wide gaps, some of which may well be bridged by the employment of the greater and better facilities for speedy aerial transport that peace will bring. These will enable specimens of pathologic tissue in fixative, virus containing material in refrigerant and chilled bacterial cultures from most parts of the tropics to be studied in the larger centers of medical research in the temperate zones within a short period of their collection. Not all of the advances in our knowledge of cutaneous diseases in the tropics are dependent on the study of morbid material in a distant laboratory. Much valuable information can be gained by careful clinical, climatologic and epidemiologic observation on the spot. An excellent example of this type of research is found in the reports of Loewenthal on the cutaneous diseases peculiar to, prevalent among or absent from native races in East Africa. It is not always easy, however, to translate data obtained by observation of one race to another, particularly when there is a lack of exact coincidence of the cutaneous histology in the two races. Such difficulty does not arise in Australia, where there is virtually no colored element at large and where comparison is possible between the inhabitants of a city in the tropics and one populated with the same stock in the temperate zone 2,000 miles to the south. Opportunity to study the course of tropical disease, free from local complicating factors, is now being afforded in the United States. An example of this kind is filariasis, in which inguinal adenopathy and scrotal and inguinal edema are not infrequently followed, in endemic filarial countries, by elephantiasis of the lower limbs or scrotum. The precipitating cause of the elephantiasis is generally believed to be the hemolytic streptococcus normally resident on the skin in such endemic areas. The higher degree of personal hygiene exercised by the inhabitants of the United States, the use of footwear and the probable lower streptococcus population of the skin in this country should therefore render much less likely the development of elephantiasis in persons who have left the endemic zone shortly after the acquisition of inguinal and scrotal manifestations of filariasis.

Dr. FRED WISE, New York. Dr. Frazier's broad experience with leprosy over a period of many years is reflected in this contribution, dealing chiefly with the epidemiology and natural history of the disease. I shall limit my discussion to the occasional difficulty of diagnosing atypical and incipient cases and the phenomena relating to tuberculoïd leprosy. Within the past three years 2 patients have come under my observation in whom the diagnosis of leprosy was entertained by myself as well as by a large group of my colleagues in New York. Both patients presented cutaneous lesions which were indistinguishable from those of leprosy. Bacteriologic, histologic and neurologic investigations, however, failed to confirm and, at the same time, failed to negate the diagnosis of leprosy. In cases in which laboratory investigations result in negative findings, the most careful neurologic examination must be done in an attempt to discover evidence of loss of sensation to heat, existence of hyperesthesia or anesthesia, analgesia and other disturbances of the nervous system. It should be borne in mind that diverse nerve changes may be present for months or years before the telltale cutaneous

manifest themselves. Thus, some cases require protracted observation and investigation before the correct diagnosis can be determined. Such instances are fortunately uncommon in this country. Dr. Frazier aptly said that "The most typical tubercles of the skin are encountered not in tuberculosis but in leprosy." If the diagnosis of certain forms of eruption should be based wholly on the histologic structure of a single lesion which happened to be of tuberculoid character, it can be readily seen that the unskilled physician's interpretation would lead to grave difficulties. Many years ago, Josef Jadassohn of Breslau established the fact that in certain cases macular lesions devoid of specific histologic structure would later undergo a transformation to a definite tuberculoid architecture. Comprehensive studies of this phenomenon have been published by Wade, Pineda, Saenz and Palomino in recent years. Wade demonstrated tuberculoid alterations also in nerves, testes and lymph nodes. Many lesions of this character, when they occur on the skin, cannot be distinguished from sarcoid, and as in cutaneous tuberculids, bacilli are either quite scarce, or none can be detected in the tissues. The immunobiologic phenomena pertaining to infection with *Mycobacterium leprae* are analogous to those of infection with tuberculosis, in accord with the Jadassohn-Lewandowsky law. A specific skin sensitization to the respective micro organisms occurs in both diseases.

GASTROINTESTINAL DISTURBANCES IN THE COMBAT AREA

II. PRELIMINARY OBSERVATIONS ON FUNCTIONAL DISORDERS OF THE DIGESTIVE TRACT

CAPTAIN ALEXANDER RUSH

MEDICAL CORPS, ARMY OF THE UNITED STATES

During a twelve month period beginning March 28, 1942 200 patients were admitted to a large hospital in the South Pacific because of "dyspepsia." Fifty-three per cent of these patients presented symptoms that were subsequently judged to be due to functional disturbances of the digestive tract. Though no organic basis for their distress could be demonstrated, these patients were found to be no less disabled than those suffering from peptic ulcer. Functional disorders constitute a major problem wherever there are large bodies of troops in the field. It is therefore considered important to record our experiences in the observation, treatment and disposition of these patients.

DEFINITION AND TYPES

Under the heading of functional gastrointestinal disease are included all those conditions in which the predominating symptoms are due to a disturbed function of the digestive tract but in which no positive objective evidence of organic disease can be demonstrated. This large group of functional disorders is subdivided into four general types based on the outstanding symptoms. Thus those patients who presented the typical syndrome of transient abdominal cramps coming on after eating and made worse by the taking of certain coarse foods are considered as belonging to a subgroup whose symptoms were due to an irritable or spastic colon. This subgroup comprises 80 per cent of the patients with functional disturbances. The next largest subgroup which accounts for 10 per cent of the total number of patients with functional disturbances, includes those whose predominating symptoms were nausea and vomiting. There is a third subgroup with symptoms similar to those of peptic ulcer who comprise 7 per cent. Finally there is a subgroup 2 per cent of the total which represents those suffering from symptoms of aerophagia.

PROBLEMS OF DIAGNOSIS

In civilian practice the diagnosis of a functional disorder at best is fraught with many hazards. In military practice these hazards are intensified not only because of the characteristic lack of positive objective findings but because of a conscious or an unconscious desire on the part of many soldiers to escape from an unpleasant or dangerous situation. For therapeutic as well as diagnostic reasons every effort was made to rule out organic lesions. Since a gastroscopic examination was not possible, the percentage figure for patients with functional disorders may include some whose primary digestive disturbances could have been secondary to chronic gastritis.

CLINICAL HISTORY

In general, a careful history, as in all cases of disease of the digestive tract, proved to be of paramount importance in reaching a correct diagnosis of functional disorders. All of the patients were found to be in a state of either acute or chronic emotional ferment. This characteristic emotional unrest was frequently found to spring from intense feelings of resentment toward a temporary local situation or from persistent feelings of anxiety or fear. These feelings often were present beneath an outward appearance of calm. When specific symptoms were considered, every sort of combination was encountered. Except in 2 per cent of patients presenting the ulcer syndrome, the most striking characteristic of functional disturbances was the food-pain relationship. This contrasted sharply with the usual pain-food-ease picture that typified ulcer in the absence of obstruction. The patient with functional disturbances complained that cramplike pains occurred shortly after meals but that they disappeared spontaneously within an hour or so or were promptly relieved by vomiting or a bowel movement. The patients with ulcer, on the other hand, commonly experienced a more or less steady pain which came on before meals and was relieved promptly by the taking of food. While this history of a food-pain relationship was helpful as a clue, it was by no means pathognomonic.

EXAMINATIONS

Physical Examination—The findings on physical examination were seldom striking. A tender and palpable sigmoid colon was encountered in approximately one third of these patients. There were no other physical findings that appeared to be at all characteristic of functional disease of the gastrointestinal tract.

Examination of Stools—With regard to color, consistency and frequency the stools presented little that could be called diagnostic. Particular attention was paid for a time to the presence of mucus, which was found in the stools of 25 per cent of these patients. This compares with 23 per cent in patients with peptic ulcer, indicating that the presence of mucus in the stools is of little importance in the differential diagnosis.

X-Ray Examination—An x-ray examination of the upper gastrointestinal tract was made in 80 per cent of our patients considered to have functional disorders. Only in 2 patients who were chronic air swallows were any findings of note demonstrated by x-ray. No significant abnormalities in emptying times were observed. Barium sulfate enemas were performed in but a small number of instances and revealed nothing remarkable. This high percentage of x-ray examinations with negative results might seem at first glance to indicate a tremendous waste of time and talent. How-

ver, in the group with functional disorders x-ray examination has proved to be of value in ruling out more serious organic lesions and to have some therapeutic advantage from a psychologic point of view

ARMY GENERAL CLASSIFICATION TESTS

The army general classification tests are designed to classify all soldiers in terms of their ability to learn their duties in the service. They are a measure of the general level of a man's abilities rather than his ability in a special field. Arrivals at recruiting centers who are able to read and write English are sorted by means of the general classification tests into five broad classes with respect to their ability to learn the duties of a soldier.¹ The following five classes have been called army grades

Army Grade I Very rapid learners, about 7 per cent of the men in the Army

Army Grade II Rapid learners, about 24 per cent

Army Grade III Average learners, about 38 per cent

Army Grade IV Slow learners, about 24 per cent

Army Grade V Very slow learners, about 7 per cent

Chart 1—Soldiers with functional digestive disease

Chart 2—Soldiers with peptic ulcer

Chart 3—Highly trained enlisted medical men

Distribution of patients with functional gastrointestinal disturbances (chart 1) and patients with ulcer (chart 2) compared with highly trained enlisted medical men (chart 3), in the army general classification grades. In each chart a comparison is made between the normally anticipated distribution (white columns) and the distribution obtained for the subjects under consideration (black columns)

Those who make high scores are usually those who do best in the various army training courses and excel in their daily duties in the service. Those who make low scores are inclined to be less alert and are likely to encounter difficulty in adapting themselves to new situations

Comparison of Army General Classification Scores

Percentage in Each Grade in Health and Disease

	Anticipated	713,000 Selectees	Hospital Personnel	Ulcer	Functional Disease
Group I	7	8	7	0	0
Group II	24	29	43	29	3
Group III	38	30	30	48	37
Group IV	24	21	12	23	32
Group V	7	12	7	0	28

The army grades on the general classification tests were computed in percentage for our patients with ulcer and the patients with functional disorders of the digestive tract. The charts graphically illustrate the findings, while the table gives a breakdown of the percentage in

each grade for four different groups of soldiers compared with the anticipated figures. The greater number of patients with functional digestive disturbances are found in grades IV and V, while the occurrence of purely functional disorders in grades I and II is extremely rare. These findings bear out in a most striking manner the clinical impression that digestive disturbances of the functional type are seldom seen among bright, alert, well integrated persons. Conversely, functional disorders of the digestive tract are more commonly seen in poorly integrated persons who have difficulty in learning and in adapting themselves to the conditions of the service. Thus from a medical point of view the selectee who on the basis of his army general classification test gives indication of being a poor risk has been so proved while under the stress and strain of field conditions in the combat area.

RESPONSE TO THERAPY

On dietary measures and the limited use of antispasmodic drugs 58 per cent of the patients with functional disorders showed no improvement. Of those

who showed good improvement 90 per cent had experienced symptoms for no longer than twelve months. A nonlaxative, low residue diet was uniformly prescribed. During the first two months tincture of belladonna 15 minims (1 cc) and phenobarbital 0.032 Gm four times a day were employed. The results were not impressive. A period followed during which these drugs were not available. While no detailed record was kept, the clinical impression was gained that the lack of these drugs made very little difference in the course of the symptoms. Recently these drugs were reinstated in treatment in accordance with the suggestion of a psychiatrist, Major John M. Cotton, M.C. Belladonna was administered in gradually increased doses to the limit of tolerance. Fifteen minims of the tincture four times a day twenty minutes before meals and at bedtime served as the initial dosage. This was raised to 16 minims on the second day, and on each subsequent day a single drop was added to each dose until relief or toxic symptoms such as blurred vision, tachycardia or excessive drying of the mouth occurred. It is too early to make any positive statements as to the value of this regimen but it can be said that the early results have been promising in overcoming the attacks of postprandial abdominal cramps.

DISPOSITION

The disposition of patients suffering from functional digestive disturbances in the field is a problem. These patients as far as physical and laboratory findings reveal have no organic lesions. In this respect they appear as healthy as the next soldier. Nevertheless they experience definite symptoms that in many instances seriously interfere with the satisfactory performance of their duties. Their ill appearances to the contrary notwithstanding are not imaginary but real. An opinion as to this type of patient's fitness for duty based on purely objective findings is obviously unsatisfactory. For this reason whenever possible further information as to the patient's military qualifications under simulated or actual combat conditions were sought from commanding officers and battalion surgeons. Information obtained in this manner was frequently found to be of inestimable value to us in reaching a decision as to the proper disposition of the soldier.

In this connection three possible courses presented themselves: (1) return to duty, (2) transfer to a labor battalion or (3) transfer to a general hospital in the zone of the interior for reclassification. After careful hospital study and education it was found possible to return to duty 88 per cent of those patients who had been admitted for the first time in contrast to 56 per cent of those with more than one such admission. The patients whom we thus returned to duty frequently were accompanied by a letter to the commanding officer explaining the findings and the nature of the disease. It was suggested that if the soldier failed to adapt himself satisfactorily and if his symptoms persisted with sufficient intensity to interfere with his efficiency he be returned to the hospital with information concerning his general fitness as a soldier.

It was learned that to keep such a soldier in his unit was detrimental to the morale of his outfit and not in the best interests of the service. An illustrative incident was reported to us of a soldier who eventually entered active combat although suffering from a functional disturbance. Under the tremendous emotional strain of being under fire his hitherto relatively mild symptoms became acute and he collapsed in a foxhole, being unable to proceed farther. He was found by two litter bearers and was placed on a stretcher. While he was being transported to a field dressing station one of the litter bearers was killed and the other seriously wounded. This seems an inordinately heavy price to pay for the health of a soldier who previously had given definite evidence of emotional instability sufficient to render him unfit for combat duty. This incident not only cost the life of a valuable litter bearer but may have prevented the evacuation of a wounded soldier in serious need of surgical care. Again this is but a single occurrence but it serves to illustrate the point that persons suffering from repeated attacks of a functional digestive disorder are more likely to be a liability than an asset under fire and for that reason should be placed from the beginning in a situation where their abilities have a greater chance of success.

During the early months the sending of such patients to a labor battalion or service company seemed a promising solution. This course was adopted with the hope that a little 'discipline' would make 'men' out of these persons. This practice we soon discovered to be disastrous. Instead of the soldier being improved he usually was returned to the hospital with his symptoms more deeply entrenched.

Recommendation for a transfer to a general hospital in the zone of the interior was made with regard to 22 per cent of the patients suffering from functional gastrointestinal disturbances by a disposition board in our hospital. When a patient of this type was readmitted because of persistent symptoms regardless of all therapy and all efforts of his command to place him satisfactorily, he was brought promptly before a board of medical officers. The majority of patients so presented, after a careful study of the man and the situation, were recommended for transfer to the zone of the interior as unfit for combat duty. How many more of our patients were similarly recommended by disposition boards in other hospitals it is not possible to say. Our figure is lower than that for soldiers who obtained certificates of disability discharge from the Lawson General Hospital as reported by Chamberlin.² It is not clear just how to account for this disparity other than that patients admitted to army general hospitals are selected in that they have been referred from other units because of serious physical defects. In contrast, the forward hospitals draw their patients directly from the troops in the field.

CONCLUSIONS

1 Patients with functional disorders of the gastrointestinal tract constitute 53 per cent of the group admitted to a large hospital in the forward area because of dyspepsia.

2 The characteristic complaint of these patients is distress induced by the taking of food.

3 The scores of the army general classification tests give striking confirmation to the clinical impression that the majority of these patients are incapable of adapting themselves to field service and are poor risks in the combat area.

4 For the most part the response of these patients to therapeutic measures in the field is transient and poor.

5 Patients who are shown to be poor learners and who persistently fail to make any satisfactory improvement should be returned promptly to the zone of the interior for reclassification.

2 Chamberlin, Donald T. Peptic Ulcer and Irritable Colon in the Army. *Am J Digest Dis* 9: 245-248 (Aug.) 1942.

Surgical Conquest of Goiter—The surgical conquest of goiter is due in large degree to Theodore Kocher who in 1872, at the age of 31, became director of the surgical clinic at Bern, Switzerland. The high incidence of goiter at Bern gave him an unusual opportunity to study the disease. Lister's method, had just been adopted by Kocher's Swiss German and Austrian colleagues, and the specter of infection in operative wounds banished. Kocher who was a master technician as well as a keen thinker devised new methods for obtaining satisfactory surgical exposure of the thyroid for controlling hemorrhage and for avoiding damage to the nerves of the larynx. In 1883 he reported his first ten years work, a total of 101 goiter extirpations with a mortality of 12.8 per cent. In this famous paper he not only described the essential features of the modern technique for removing thyroid adenomas but he identified a new clinical condition which he called *cachexia strumipriva*. All but two of a series of 18 patients in whom he had removed the entire thyroid developed a syndrome characterized by lethargy, puffiness of the face and drooping of the skin. Kocher rightly concluded that this was due to a lack of thyroid secretion—Hargraves C. D. and Lloyd Wainman J. P. A Hundred Years of Medicine. New York: Sheridan House Inc. 1943.

Clinical Notes, Suggestions and New Instruments

BICORNATE UTERUS WITH PREGNANCY IN EACH HORN

MAJOR ALEXANDER BRAZE, MEDICAL CORPS
ARMY OF THE UNITED STATES

During the embryologic development of the female the two müllerian ducts fuse from below upward to form the vaginal tract and the uterus. The numerous anomalies of the female genital system that have been reported in the literature can be ascribed in the great majority of cases to lack of fusion at any location throughout the extent of the two canals and in the remainder to the rudimentary development of one duct.

In various animals the müllerian ducts normally do not fuse and consequently two tubular uteri are present. In the human being in the event of incomplete development of one duct, the rudimentary side appears as an appendage to an apparently normal uterus. Since Mauriceau and Vassal reported the first case in 1669 over 100 cases of varying degree and extent have been described in the literature.

Usually menstruation occurs from the two uteri simultaneously, however it may come from one horn at a time. Pregnancy may occur in one or both horns. Muller has recorded cases of menstruation from the empty horn during the pregnancy. In one instance twins were found in one horn. It is conceivable that should each horn contain an ovum, superfetation might occur. Several such cases have been reported in the literature.

In the ordinary course of events pregnancy in one horn is undisturbed the uninvolved or nonpregnant horn growing and forming a decidua membrane typical of that found in an ectopic pregnancy. In some cases this decidua may be expelled without disturbing the pregnancy of the other horn. In other instances the course will resemble that of an abortion for which the usual treatment is instituted. Being forewarned as to the presence of an anomalous development of the uterine tract, the surgeon proceeds with extreme caution during the curettage.

The sparsity of reports which have been recorded indicate that it is unusual for gestation in a bicornate uterus to continue uneventfully to term. Should this occur, the following complications are quite frequently encountered:

1 Weak pains may occur associated with atony in the third stage with resultant postpartum hemorrhage.

2 Dystocia may be produced by prolapse of the nonpregnant horn under the other with incarceration in the pelvis or by the nonpregnant cervix being forced downward to the vulva with the head.

A review of the literature has revealed a definite lack of adequate reports on pregnancies in each horn of a bilateral uterus and in no instance successful termination of such pregnancy with viable children.

In 1925 Rowlett¹ of Florida described a case of a double uterus with pregnancy of each horn. The condition had been

discovered during a laparotomy two years previously. Despite this knowledge the patient went into labor after five months' gestation miscarrying male fetuses weighing 3 pounds 4 ounces (1,420 Gm) and 2 pounds 3 ounces (990 Gm). The question of superfetation was raised.

In 1933 Wong² of the Peiping Union Medical College in Peiping, China, reported in considerable detail a pregnancy

Fig. 2—Appearance after intrauterine injection of iodized oil six weeks post partum.

in one horn of a double uterus. At six months there occurred all the signs and symptoms of a miscarriage ending in expulsion of a decidua cast of the nonpregnant horn. Convalescence was uneventful, and three and one-half months later the patient was delivered of a normal girl baby. The puerperium progressed normally. A special examination forty days post partum attempted to prove by hysterosalpingographic studies the presence of a bicornate uterus. After repeated attempts Wong and his associates were able to demonstrate only the right uterine cavity and its tube. One week later the test was repeated and both cavities were demonstrated. There was only one cervical canal, and the opening into the left uterine cavity was just within the external os and so was passed by the cannula on previous tests.

In 1934 Barrett³ of the Vanderbilt University Hospital in Tennessee reported a bicornate uterus with a pregnancy in each horn. Both infants were born prematurely and died shortly after delivery. The patient had had six previous pregnancies of which three aborted and two miscarried (one of twins). One pregnancy went to term, producing a girl who was 5 years old at the time of the reported pregnancy.

In 1939 Johnston⁴ of Akron, Ohio, reported a case of a dead fetus in one cornu and a normal pregnancy in the other. The condition was discovered during a laparotomy in which the cornu with the dead fetus was mistaken for a fibroid and removed. The remaining pregnancy continued uneventfully to term, and the delivery of a full term normal infant was accomplished with low forceps.

- 2 Wong, Amos, I. H. Pregnancy in a Double Uterus. J. Am. M. A. 47:6163, 1933.
- 3 Barrett, Arthur B. Bicornate Uterus with Pregnancy in Each Horn. J. Obst. & Gynec. 28:612 (Oct.) 1934.
- 4 Johnston, W. M. Bicornate Uterus. Am. J. S. 11:111, 1939.

The case which I present is of particular interest since it represents the only recorded case in the literature of pregnancy in each horn of a bicornate uterus which proceeded uneventfully to term with consequent delivery of two normal viable children.

REPORT OF CASE

On Jan 20, 1941 at 8 a m Dr J S Lundholm referred to me Mrs R T, white, aged 24, who was in active labor. Her menstrual history was normal (last menstrual period April 8, 1940) although her menses had been extremely profuse. One year previously she had had a delivery in the home. The membranes had ruptured spontaneously prior to the onset of labor, which continued with severe dystocia for twelve days, resulting in the delivery of a female child which lived for only a few hours. The dystocia was undoubtedly produced by the incarceration in the pelvis of the nonpregnant horn.

Examination revealed an extremely broad abdomen containing two sets of fetal heart tones 140 per minute on the right and 135 on the left. Both fetal heads were palpable and the diagnosis of twins was readily made. There appeared to be a depression between the two fetuses, a fact which aroused a suspicion of the presence of a bicornate uterus. Inspection of the introitus revealed a third degree cystocele and rectocele. According to the roentgenologist's report, a flat posteroanterior film of the abdomen showed the presence of twins. The two fetal heads were floating above the pelvic inlet. Both heads

examination there were apparent two widely separated uterine bodies with no definite palpable point of fusion.

Hysterosalpingographic studies were undertaken on March 6, 1941, approximately six weeks post partum. Fifteen cc of iodized poppyseed oil was injected through the cannula, which was inserted so that the tip rested just within the external

Fig 3—Posterior view of surgical specimen

Fig 4—Anterior view of surgical specimen

cervical os. The roentgenologist reported that a flat film of the pelvis made after an intrauterine injection of iodized oil showed a bicornate type of uterus filled with a radiopaque material. The cannula extended into the right uterine horn for a distance of 15 cm. The horns of the uterus were about 3 inches in length. This increase in the size of the uterus was probably due to subinvolution. The fallopian tubes contained some radiopaque material but were not abnormal (fig 2).

Fig 5—Sagittal section of surgical specimen

were presenting one on each side of the pelvis. The fetal spines were directed laterally and the small parts were directed toward the maternal spine. There were no developmental anomalies of the fetuses or of the maternal pelvis. Both of the fetal heads appeared to be attempting to enter the pelvis. There was evidence of pressure on both heads, which is not unusual during labor, but the pressure on one of the heads appeared to be due to the other head pushing against it (fig 1).

At 10 a m there occurred a relatively simple spontaneous delivery of a viable 5 pound 12½ ounce (2620 Gm) boy. The placenta was delivered intact at 10 12 a m from the right horn, but, despite firm contraction of this horn profuse hemorrhage continued. At 10 19 a m a living 6 pound 9 ounce (2860 Gm) girl was delivered by manual pressure over the left fundus and its placenta followed intact at 10 25 a m. The left horn remained atonic but with continued gentle massage and the administration of pitocin and ergotamine tartrate (Mergin) eventually contracted nicely. Two firm masses were palpable in the suprapubic region. There were no lacerations. Profuse hemorrhage again occurred at 1 p m but responded well to treatment.

The blood count of the mother revealed a hypochromic anemia of pregnancy (hemoglobin 38 per cent and red blood corpuscles 2910000). She was given a transfusion of 550 cc of whole citrated blood. The puerperium was otherwise uneventful.

On the seventh postpartum day a vaginal examination was performed under aseptic technique. Specular examination revealed a single cervix and no vaginal septum. The third degree cystocele and rectocele were of course still present. On bimanual

The mother and twins were dismissed from the hospital in excellent physical condition in two weeks. The twins are still alive at the time this paper is being written and are progressing normally.

Approximately three months following her dismissal from the hospital the patient was readmitted with severe lower

abdominal cramping. Pelvic examination revealed a firm tender mass in the left fornix which could not be displaced upward. A diagnosis was made of prolapse of the left horn of the uterus with incarceration in the pelvis. Since the patient had two healthy children and her financial status did not warrant prolonged conservative treatment, surgery was instituted after a preliminary blood transfusion. An anterior and posterior colporrhaphy was first performed to repair the pelvic floor and then the abdomen was opened by means of a midline suprapubic incision. The incarcerated fundus was relieved with some difficulty. The uterus then presented itself as two widely divergent horns each with its own tube and ovary and with no visible site of fusion. The body of the uterus was then removed in toto the process revealing the site of fusion to be just above the internal cervical os. The pathologist reported that the specimen was a uterus weighing 85 Gm. The uterus had two bodies and one cervix. The bodies were entirely separate except at the point of union with the cervix. They were cylindrical and measured 35 and 30 cm in diameter. The uterine canals were not enlarged and were lined with velvety smooth pink endometrium. The muscle walls averaged about 1.5 cm in thickness. The cervix presented no important changes. In order to save the specimen, no sections were made. They were considered unnecessary. The diagnosis was uterus bicornis unicollis (figs. 3, 4 and 5).

The patient made an uneventful recovery and has had no further difficulty.

THE USE OF BIODYNE OINTMENT FOR BURNS

JOHN WINSLOW HIRSHFIELD, M.D., MATTHEW A. PILLING, M.D., AND
MARK F. MAUS, M.D., DETROIT

Bio-Dyne ointment has been publicly advocated for the treatment of burns.¹ In recent articles in the lay press it has been claimed that burns so treated heal painlessly and with remarkable rapidity. It has been stated that the ointment contains substances which stimulate epithelial proliferation. These public claims have resulted in inquiries by many patients and often in the demand that Bio-Dyne be used by physicians. If Bio-Dyne ointment has these properties, it represents a truly remarkable advance in burn treatment. Since, however, we were unable to find in the medical literature any experimental or clinical support for these claims, we decided to study the effect of Bio-Dyne ointment on fresh wounds of experimental animals and man.

In order to test the epithelial growth stimulating effect of Bio-Dyne as compared with petrolatum, these ointments were applied to fresh wounds made by removing the epidermis with the Padgett dermatome. These wounds of uniform depth must reepithelize themselves primarily from the epithelium of hair follicles and the sebaceous and sweat glands of the dermis. They are ideal for testing a substance designed to stimulate epithelial growth. Two such wounds were made on each of 8 dogs, on 8 domestic pigs, and during the course of skin grafts on several human beings. Hence it was possible to treat a control wound with petrolatum impregnated gauze and the other wound with Bio-Dyne ointment. Specimens were removed for microscopic examination before application and at intervals after the application of Bio-Dyne ointment or petrolatum. Each time the dressing was disturbed for removal of a specimen a fresh supply of Bio-Dyne ointment or petrolatum was put on the wound. The specimens were fixed in solution of formaldehyde and stained with hematoxylin and eosin. Specimens were taken from dogs and pigs at intervals from 6 to 192 hours. We were able to persuade only 2 patients to submit to excision of tissue for examination, and therefore human material is limited to 2 microscopic observations, one at 4 and one at 5 days. However, the clinical course of several additional patients could be observed.

Examination of the wounds of man and animals revealed no evidence that Bio-Dyne accelerated the healing process.

From the Department of Surgery and the Surgical Service of Receiving Hospital, and the Department of Pathology of Wayne University College of Medicine.
1 New York Herald Tribune July 18, 1943. Time Magazine 40 94 (Oct. 5) 1942. Reader's Digest 42 75 (Jan.) 1943.

The wounds treated with Bio-Dyne and those treated with petrolatum gauze healed in the same time. The dressings were more painful in the wounds treated with Bio-Dyne because the Bio-Dyne ointment seemed to dry or to be absorbed, leaving the gauze dry, stiff and adherent to the wound. The gauze impregnated with petrolatum remained greasy and was easily removed.

Examination of the prepared slides confirmed the clinical impression that Bio-Dyne failed to promote epithelization more rapidly than petrolatum gauze. In view of the lack of evidence that Bio-Dyne accelerates epithelial growth, we are not convinced that Bio-Dyne ointment has any advantages over petrolatum gauze for the treatment of burns.

Special Article

THE ABATEMENT OF NOISE

CAREY P. McCORD, M.D.

AND

JOHN D. GOODELL

DETROIT

It is a commonplace fact that the nation's present circumstances of living and working have greatly multiplied both the quantity and the continuity of noise. At the same time justification for noise seems better established so that indignation, however warranted, meets some disfavor. If the period of national stress may so accentuate the ill effects of noise that a disturbed people will demand and secure relief both for the duration of the conflict and thereafter, at least one constructive end will have been attained.

When expanded industrial plants operate on three shifts instead of the customary one day-shift, their contribution to the noise and the ill effects of noise throughout the community may be enormously increased. Automobile traffic may be as heavy at midnight as at 5 in the afternoon. Increased numbers of streetcars, replacing unfueled automobiles and operating continuously, may make both days and nights unendurable. Recreation through noisy sports at 2 o'clock in the morning may seem reasonable to those workers whose tasks were completed at midnight, but not so for those other workers then seeking sleep with duties beginning at 7. In turn, each group disturbs some other. Organized night trucking, planned to avoid daylight road congestion, perpetuates the din of the day throughout the night.

The acceptance of noise as an inescapable necessity possibly reflects unintelligent complacency. A proper understanding of the established ill effects of noise and the practicability of noise control would appear to warrant sponsorship of noise abatement as a second war measure. The purpose of this report is to assert that much current noise is needless, that effort against noise is a widely neglected but legitimate portion of over-all warfare, that methods of noise control are practical and no longer technically mysterious, and that behind some of the more publicized evils of the day such as wilful absenteeism, may be found the inordinant disturbances from noise.

This publication represents a report of the American Medical Association's Committee to Study Air Conditioning conditions of the Detroit area. Chairman, Dr. Walter M. Simpson, Detroit; members, Dr. P. McCord, Detroit; Dr. Walter M. Simpson, Detroit; Dr. Prof. Constantin P. Yaglou, Boston; and Dr. Alan I. Lurie, New York, together with Mr. John D. Goode, Detroit.

A PREFATORY STATEMENT OF NOISE ABATEMENT
PRINCIPLES

Every successful suppression of noise results from the application of one or more of a large number of somewhat unrelated principles. None may be described in detail, but some of the fundamental laws are explained sufficiently to provide background for the specific examples in the tabulation which follows and the suggestions appearing in various sections of this report.

Fundamentals—1 Frequencies which produce auditory impressions are propagated by means of pressure waves. When a vibrating body strikes a series of rapid physical blows against the air, wood, metal or whatever substance with which it comes in contact, this impact is either cushioned or transmitted in direct proportion to the mass per unit of volume of the material which receives the blow.

2 Just as an electrical circuit presents an impedance to the flow of current so the cross section of an acoustic conductor presents an impedance to sound energy. The most efficient transfer of energy between two mediums occurs when the impedances are matched.

3 Every object which can be set into vibration so as to generate audible energy has a natural period of oscillation. This means that if it is stroked, struck or plucked it will always generate a sound wave containing the same fundamental frequency.

4 When a sound wave is generated in the open air, it continues to travel until the energy is dissipated. When a sound wave is generated within a room, it is reflected from the walls, ceiling, floor and furnishings, the energy finally being dissipated during countless journeys between reflecting surfaces. A human being in the room receives an auditory impression of the sound on each reflected journey past his ear. The intelligence is conveyed by the original impulse, the rest is a confusing jumble. Listening to speech under reverberant conditions is like trying to watch motion pictures in a room constructed entirely of mirrors.

Related to reverberation, but not identical, is the "focusing effect" of certain structures. By focusing effect is meant the tendency for large amounts of reflected sound to arrive at the listening point from directions other than that of the source in such a manner that reinforcement takes place.

Acoustic treatment of ceilings and walls has relatively little value in reducing low frequency reverberation.

We have conducted a series of experiments in connection with the elimination of noise, particularly with respect to low frequencies. If two sound waves of equal intensity and frequency coincide in such a manner that the compressions of one correspond to the rarefactions of the other, they are said to be in opposite phase and the result approaches silence. This curious effect where two sounds are subtractive may be used to advantage in noise reduction.

The experiment performed is presented graphically in the accompanying illustration. The sound source in the center radiates a wave of specific low frequency. The highly directional microphone (B) is placed a short distance away facing the sound source. The output from the microphone is fed through an amplifier to the four loudspeakers, which are housed in directional baffles faced away from the sound source. The amplifier is designed with electrical filters to eliminate all frequencies except those which the system is designed to cancel. The elements of the system are so arranged that the sound wave from the speakers occurs, 180

Tabulated Principles and Examples of Their Application

PRINCIPLE	APPLICATION
1 When a physically small object such as a piano string is set into vibration it presents a relatively tiny surface to the air. If it is in firm contact with a large acoustic conductor such as the sounding board of a piano the transfer of energy is more efficient and results in effective physical amplification. Acoustic isolation of small vibrating bodies from all conductors and sounding board surfaces is desirable in minimizing noise.	1 An example of this principle concerns the sound output of a watch resting on a tabletop. The tabletop will function as a sounding board producing sufficient amplification to make the sound output disturbing to sleep. The same watch suspended from its chain might be almost inaudible. Another demonstration of this may be made with an ordinary dinner fork. If one holds the fork in the air and plucks the tines the sound will be puny. The instant one touches the handle of the fork to the table the sound is increased amazingly.
2 The deliberate mismatch of impedances for purposes of minimizing noise transmission may be applied to the construction of walls. Associated with this approach is the desirability of using non elastic materials for constructions that may function as undesirable transmitters.	2 Walls should be built of materials with high density and mass the impedance of which is great compared with that of air. Proper installations of insulating materials in wall suspensions and between partitions the impedance of which differs greatly from that of the walls are also valuable. Plywood is an example of unsatisfactory wall material because of high elasticity and low mass. Concrete may be desirable because of opposite characteristics. Certain fibrous materials may be useful in spite of their low mass and density because of their low elasticity.
3 Sound conditioning and air conditioning are closely related projects. With the elimination of the necessity for open windows to provide ventilation it becomes possible to isolate the interior of a structure from almost all exterior noise.	3 Noise reduction is a direct result of air conditioning in public conveyances as well as in structures. An obvious example of this appears in modern streamlined trains where air conditioning has brought about greatly increased insulation against noise. This unquestionably is a factor in the decreased fatigue of passengers on these improved trains.
4 The experimental results of many investigators have shown that injury may result from bone conducted sound. Protection from injury by acoustic energy transmitted through the floor may be obtained through rubber soled shoes insulated platforms for workers and isolation of energy sources by means of cushioning supports.	4 In this connection it is important that the isolating material be adequately loaded. In other words it is possible to use such a large mat of rubber under a working platform that the weight it carries will only slightly compress it. In this case the rubber mat may be so springy as actually to increase the vibration energy transmitted to the worker.
5 In some cases relatively quiet operations or devices may be substituted for those causing noise.	5 Welding may be used instead of riveting e.g. in shipbuilding or trical vehicle manufacture. Light signals are often a practical substitute for telephone bells and other noisy devices intended to attract attention.
6 Under certain conditions a small percentage of reverberant noise may serve as an isolating medium. In an absolutely quiet room the continuity of a worker's thought is disrupted by the overheard irrelevant intelligence in nearby conversation. In a slightly reverberant large office such sounds are blended in the general noise level and the distraction is decreased.	6 It is not always desirable to partition large offices. When several people are working in proximity a low general noise level serves to mask the intelligibility of nearby conversation.
7 Percussive sounds particularly intermittent ones of high frequency are a source of pronounced irritation. In many cases the elimination of a few such seriously annoying sounds will satisfactorily reduce the fatigue of workers.	7 In order to avoid the intermittent rattle of loose parts on machines friction of an unoled surface against another regular maintenance work on machinery and the damping of unnecessarily vibrating parts are indicated.
8 Under circumstances in which the original sound wave is generated at high intensity (80 decibels or more) the prime effect should be directed toward reducing the intensity of the sound at its source.	8 Reduction of audio energy sources may be accomplished by the application of several principles mentioned elsewhere.
9 In a reverberant room the decay of a sound wave is low and succeeding impulses may occur while reflections of the original impulse continue. In this case a sound level is established which may greatly exceed the level which would be attained without reflection.	9 The installation of acoustic material on the walls (or elsewhere) will reduce reflection of sound waves. The increased use of carpets wall hangings and drapes will serve this same purpose but a larger amount is required to obtain the same result.

degrees out of phase with the wave from the sound source and produces cancellation. It is believed that this method of noise elimination may be applicable to certain previously difficult problems particularly under outdoors or nonreverberant conditions.

NOISE ABATEMENT IN INDUSTRY

It may not be shown that all industries are disturbingly noisy but in a recent prewar publication 467 occupational pursuits out of a total of 7 000 were listed as clearly contributing undesirable noise output. This figure fails to indicate the total probable exposure, since many noise free operations are customarily carried out in proximity to noisy ones. As a rule the architecture of manufacturing plants is such as to accentuate reverberation.

Chiefly from industrial experience it is now accepted as established that noise produces significant deafness

Subtractive effect of sound waves in opposite phase

both on a functional and on an organic basis, that noise causes or contributes to pathologic fatigue and that noise under some circumstances lowers the work output. Less certainly established, but probable, are the indications that noise unduly contributes to absenteeism, increases work spoilage and generally hampers the worker, and especially the new worker in job adjustment. It is known that in a few trades all, or nearly all, old-time workers suffer varying degrees of deafness. It is deplorably true that heavy forge operators are so nearly universally impaired as to hearing that partial deafness is recognized as some proof of experience in the trade.

One typical noise problem, together with its remedies, is here presented as generally illustrative, but particularly illustrative of the fact that steps other than wall and ceiling treatment may be required in many situations. This example is slightly disguised for military reasons. In a certain plant engaged in the manufacture of steel balls (each weighing about three-fourths of an ounce), with a weekly output to be reckoned in

millions, it became necessary to carry out visual and automatic inspection for defects and size. In the visual inspection process the balls were scooped up from sheet metal baskets and dropped onto metal tables. After inspection the balls were tossed by the score or more of inspectors into various metal containers depending on the nature of the defect. Nearby, the size inspection was carried out by several automatic machines. In all instances the balls poured from large hoppers into smaller ones, thence traveling through chutes to sizing rolls, the various sizes falling on other metal chutes and ultimately dropping into a series of metal boxes. The total output of noise was horrendous. The area of greatest annoyance was not immediately in this workroom but in adjacent offices separated only by thin partitions.

To abate this noise to reasonable comfort proved to be comparatively simple, using easily available materials and methods that might be carried out by average plant personnel and facilities. The following steps proved adequate:

All portable sheet metal containers were changed to wood.
All table surfaces were covered with plywood.

All chutes were lined with leather.

Vibration of the metal hoppers during the refilling process was decreased by refilling when half empty. This increased the inertial mass and damped the vibration tendency.

The under side of all other sheet metal surfaces over which the steel balls traveled was damped by a thick undercoating of quick drying mineralized paste.

All piping throughout the department was insulated.

Lastly, and by this time not altogether necessary, a double wall partition was erected as a protective barrier for adjacent offices. This wall was so constructed as to be "floated" rather than being built integrally into the general structure.

Through almost endless variations, noise problems arise in industry. For most of these situations there exist little used, but no less practical and simple remedies. It is fallacious to claim that workers become injured to noise. They may become injured on the basis of deafness, but any psychologic adjustment of noise that may appear to take place must be reacquired on a day by day basis. Heretofore, compensation for injury in industry has largely excluded such disorders as occupational diseases. Whatever merits reside in broadened compensation provisions that characterize some new laws, it must be reckoned that increased impetus will be given thereby to the better control of injurious noise in industry.

NOISE ABATEMENT THROUGH ARCHITECTURAL FEATURES

Present and prospective needs inescapably require a wider application of architectural noise prevention. Every structure designed for the housing of the activities of human beings will represent architectural imperfection in the absence of appropriate noise control features. Apart from a somewhat restricted field of noise treatment, the building trend distressingly favors more, rather than less, noise. High costs both of material and of labor make some flimsy construction of small residences almost inevitable. As street noise increases, obviously there is need for greater insulation. To accomplish noise privacy it becomes necessary to provide two structural features: (1) a design of structure so as to prevent the transmission of sound from exteriors and between rooms, (2) sufficient absorption within rooms that the reverberation will not be excessive. Contrary to some popular

pseudo architectural concepts, these are two distinct matters requiring individual solutions

Walls should be constructed of materials of high density and mass. Walls of this nature will function as excellent conductors of sound but, because of their extremely high impedance and low natural frequency, will be very difficult to set into vibration and hence will not become secondary noise sources. In order that a wall may transmit a sound to the air in an adjacent room, it must function not only as a conductor but as a projector or radiator. Hence, what would appear to be a fallacy in the use of highly conductive materials to provide sound insulation between rooms is actually desirable.

Many people believe that heat insulation and sound insulation entail identical solutions. This is not entirely true, although most porous materials provide good heat insulation and also have desirable sound absorptive qualities. Measurements of the insulation provided by porous materials indicate that they have relatively little value by themselves unless they are extremely thick. These materials are most effective in sound insulation when they are supported in an air space between two rigid partitions. Properly installed they will contribute considerably to the over-all insulation provided by a wall.

MISCELLANEOUS ITEMS

Utter silence, apart from certain laboratories, motion picture studios and a few other places is never the objective of noise abatement. Human adjustments are such that total sound absence is disturbing, and any break in the silence is then startling and at times terrifying. A low background of 20 to 30 decibels of sound is comforting rather than annoying.

In industry the satisfactory operation of many machines is determined by the ears of the operator. Conscious effort in the detection of these telltale sounds constitutes the chief complaint of many workers against ambient noise. The situation is akin to that in medicine when auscultation is made impossible or difficult by surrounding noise.

Music during work may be advantageous under some circumstances and anathematous under others. In work, every job may lead to rhythmic muscular motions—every job having its own variations. The varying tempos of music may wholly upset job rhythms, reduce production and indirectly cause accidents.

Good types of ear defenders, properly fitted, may reduce loudness of ambient noises as much as 80 per cent at certain levels without interfering with the opportunity for ordinary conversation. While the molded fitting of an ear defender is highly desirable, the taking of ear canal impressions followed by the casting of individual stoppers for each ear of all individuals introduces many practical difficulties.

During exposure to injurious noise levels the larger part of the hearing loss occurs during the first hour, with only slight elevation during subsequent periods. On the other hand recovery time is definitely prolonged if the exposure time has been extensive. Roughly, the apparent recovery time is proportional to the square of exposure time but cumulative effects repeatedly have been demonstrated.

While sounds that are not loud may be the source of some physiologic damage and annoyance probably only loud sounds cause organic damage to the ear.

Older persons are more likely to incur auditory apparatus damage from noise since their hearing organs possess lower recuperative powers.

Wide variations exist in different people in sensitivity to noise. Relative tolerance to noise is an acceptable concept.

In the average factory with mechanical operations, the noise level is approximately 90 decibels, or 10,000,000,000 times the least perceptible sound and 100,000 times the sound of ordinary conversation.

Holes in walls, such as for the previous passage of pipes, permit the passage of much unwanted sound. Even a key hole may transmit sound energy sufficient to warrant suppression. Under these circumstances a constriction of the sound stream takes place so that more energy passes through than might be expected. Any open air passage of any size may be of importance in reducing the transmission of noise between rooms.

Fluctuation in noisiness is experienced unpleasantly. A continuous noise from 70 to 75 decibels is endurable, an occasional increase from 40 to 70 decibels may be much more annoying.

On a psychologic basis, much discomfort arises from noise expectation. If one shoe is dropped on the floor above and the interval pending the fall of the second shoe is excessive, the tension produced by the observer's expectancy constitutes a minor example of this type of disturbance.

High frequency sounds produce greater acoustic trauma than those of low frequency, but in the long run low frequency sounds may offer greater problems because they are less easily abated. It is pointed out that trauma which is actually caused by an abrupt change in barometric pressure may be mistakenly attributed to the low frequency sound e. g. in drop forge operations where a large hammer displaces a considerable cubic quantity of air so suddenly as to create a destructive pulse of increased barometric pressure.

In the operation of large guns, it has been shown that the effects of shock and deafness result from the primary pulse of air pressure rather than from the sound modulation of the air. The effects are closely related to the duration of the compression pulse, which is usually much shorter than the rarefaction. In comparative tests made with rifles and mortars it was found that the compression pulse from the mortar was of much higher pressure but that the malleffects were minor because of the relatively short duration of the explosion pulse from the mortar.

It is believed that, where explosive shells are intended to produce shock in personnel not subjected to direct hits the fact that extreme explosive pressures of short duration often do not produce serious trauma while relatively low pressures of longer duration have great effect should be an important designing consideration.

Ear defenders are valuable in protecting the ear from dangerous noises associated with gun fire but may not provide protection against explosion shock.

LEGISLATIVE ASPECTS OF NOISE ABATEMENT AND NOISE PREVENTION

The control of noise by municipal or higher authority never has been wholly effective. Effectiveness will never be attained until there comes a time when both the public and

responsible officials have acquired better concepts of the significance of noise and the measures through which noise may be eliminated or reduced to inoffensive levels. The vague outlawing of the barking of dogs or the shrieking of newsboys becomes unimpressive in the face of tolerated streetcar systems that may be a thousand times more annoying, or the licensing for operation of loud speakers on trucks which rove the streets day and night shouting the dubious values of possibly questionable products or causes. Legal measures as commonly written are frequently so loosely phrased as to permit numerous interpretations and hamper enforcement. Customarily, only on complaint of disturbed citizens is consideration given to obviously disturbing noises.

Education of the public as a whole and in special groups along with necessary legislation appears to be the key to noise amelioration. Many law abiding citizens who under no circumstances would contemplate the sending up of a rocket flare on a public street or turning a flood light on an apartment house to attract the attention of a friend will unhesitatingly blanket a house and an entire block with resounding noise from a badly designed automobile horn. It seems necessary to carry out educative programs as a supplement to legislative acts for the general public, for the makers or purveyors of noisy devices and particularly for architects and builders of various structures such as homes, hotels, office buildings and streetways.

In a previous sentence the term "badly designed" was deliberately used. In the design of automobile horns there appears to have been overlooked the fact that many accidents are unnecessarily caused by fright or confusion from the alarming intensity of the automobile horn. In recent years some horns have been redesigned to play a tune, which unduly prolongs the sound.

It is possible so to train a dog that on hearing a specific sound he will immediately wag his tail or lift a foot or perform some other reflex indication of awareness. It should not be more difficult to educate the public to respond to simple, nonirritating sounds as a warning of vehicular danger. It is obvious that a human being educated to the dangerous significance of a specific sound will react to protect himself more intelligently and more expeditely than in the midst of fright from nearby shrieking noises. It is understood that the Sparks-Withington Company has studied this problem with a view toward designing an improved automobile horn.

Designers of modern railroad locomotives have demonstrated the advantages of the mellow horn now used on diesel locomotives over the shrill steam whistle. It is actually easier to locate the direction of approach from this low pitched tone, and the countryside and cityside are spared the affront that formerly echoed from all directions.

Most legislation has failed to include provisions in building standards for protection against noise. In some measure sound abating materials are relatively cheap, but failure to specify their use or the method of application has made many buildings hideous as to abode or work because of noise disturbances. The monetary value of acoustic insulation from street noises is well recognized in some hotels where it is found

that the public will pay increased rates for rooms on higher floors or for spaces that have been properly treated acoustically.

The continued use of noisy streetcars lends affront no longer to be tolerated as a necessary evil, except under the immediate conditions imposed by war. In many cities, busses or other streetcar substitutes have measurably reduced this annoyance. Distinct advantages are to be found in the "PCC car," a quiet type of streetcar developed several years ago, the construction of which is open to all car builders throughout the country. It is believed that PCC car construction has been hampered sharply by war circumstances, although large numbers are already in use in many sections of the country. It is noteworthy that in the presence of a quiet streetcar the noise of the trolley wheel, previously unnoticed, becomes annoying, and in some instances led to the substitution of trolley shoes. This is a good example of the oft encountered experience that with the elimination of a principal noise there rise other irritating noises previously masked.

At this time a number of cities, large and small, under the aegis of the National Noise Abatement Council or otherwise are carrying out noise control programs. The patterns of these programs are similar emphasizing publicity and education. In some instances achievements are sought on an intercity competitive basis. In addition to immediate accomplishments such campaigns will contribute to the groundwork required for more directly constructive measures.

Noise curbing activities in New York City may be referred to as an outstanding rather than representative example. In that city in one recent year 225,143 persons were issued warnings under the provisions of the Noise Abatement Code and 32,282 others were given court summons. Some of the bans included in the New York provisions are

To sound any horn or signal device on any automobile, motor cycle, bus, streetcar or other vehicle while stationary, except as a danger signal when an approaching vehicle is apparently out of control, or, if in motion, only as a danger signal after or as brakes are being applied.

To blow any steam whistle except to give notice of the beginning or stop work, or as a warning signal.

To operate any radio, phonograph or any musical instrument in such a manner or with such volume as to annoy or disturb the quiet, comfort or repose of persons in any dwelling, hotel or other type of residence.

To erect, demolish or alter or repair any building other than between the hours of 7 a. m. and 6 p. m., except in case of urgent necessity.

To use mechanical loud speakers or amplifiers on trucks, etc.

Measures of this character may be found in many cities, but it is not believed that equal activity in enforcement always prevails. The need for these curbing procedures is most clearly indicated during war-time, but they should be considered as long range projects.

EPITOME

Patient endurance of excessive and perpetuated man-made noises is no longer a virtue. Injury, measurable and immeasurable, from noise such as noise which attends human life is real and not a matter for consolation. Relief from noise is procurable.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

Anti-Trichomonas Vaginitis Agents

THE COUNCIL ON PHARMACY AND CHEMISTRY FREQUENTLY GIVES CONSIDERATION TO CLAIMS ADVANCED ON BEHALF OF PRODUCTS PROPOSED FOR THE TREATMENT OF TRICHOMONAS VAGINITIS. BECAUSE OF SUCH CONFUSION WHICH EXISTS ON THIS PROBLEM THE COUNCIL DECIDED THAT A STATUS REPORT SHOULD BE PREPARED. SUCH A REPORT MIGHT PRESENT AMONG OTHER THINGS A REVIEW OF THE CLASSES OF COMPOUNDS NOW IN COMMON USE AND THE TYPE OF EVIDENCE NECESSARY TO EVALUATE AN AGENT OR PROPOSED TREATMENT. OBVIOUSLY, MANY FACTORS MAY AFFECT SUCH A REPORT. INVESTIGATORS MAY BE INFLUENCED BY THEIR OWN IDEAS AND OPINIONS. MANY PATIENTS WITH TRICHOMONAS VAGINITIS ARE NOT DISTURBED BY THE PARASITISM AND MANY OTHERS IMPROVE OR EXPERIENCE SPONTANEOUS CURES IN A MATTER OF MONTHS. TOO OFTEN THERE ARE NO CONTROL STUDIES IN CASES WHICH FAIL TO IMPROVE SPONTANEOUSLY, FREQUENTLY BECAUSE THE PATIENT IS INSISTENT THAT SOMETHING BE DONE AT ONCE.

FURTHER DIFFICULTIES IN OFFERING CRITERIA FOR CURE OR FOR THE EVALUATION OF A DRUG ARE CONCERNED WITH THE EXISTING UNCERTAINTY OF THE ACTUAL ORIGIN OF THE DISEASE AND THE PROBABLE MULTIPLE AND VARIED CHANCES FOR REINFESTATION. WHILE SOME PATIENTS IMPROVE WITH ANY TYPE OF SIMPLE TREATMENT AND OTHERS BECOME ASYMPTOMATIC SPONTANEOUSLY, STILL OTHERS, ESPECIALLY SOME OF THE RECALCITRANT ONES, IMPROVE WHEN THE NUMBER OF AND THOROUGHNESS OF APPLICATION OF TREATMENTS ARE DECREASED.

A REVIEW OF MANY REPORTS IN MEDICAL LITERATURE REVEALS A COMMON FAILING: METHODS OF TREATMENT ARE DESCRIBED BUT WITH VERY INCOMPLETE DATA ON NUMBER OF PATIENTS, NUMBER OF CURES (COMPLETE), RECURRENCES, NUMBER AND LENGTH OF TREATMENT. IN RELATIVELY FEW CASES ARE COMPARISONS OF DIFFERENT METHODS MADE OR CONTROLS EMPLOYED. THE NUMBER OF PAPERS THAT DO NOT REPORT ANY FAILURES IS SURPRISING. YET REGARDLESS OF THESE FACTS MANY CLAIMS ARE MADE FOR THE THERAPEUTIC EFFICACY OF INNUMERABLE AGENTS. TO EMPHASIZE THE INADEQUACIES THAT MAY EXIST THE DIFFICULTY OF SETTING UP SATISFACTORY EVALUATION CRITERIA WITH OUR PRESENT KNOWLEDGE AND TO SETTLE SOME OF THE UNCERTAINTY WHICH IS APPARENT IN MANY LETTERS OF INQUIRY ARRIVING AT HEADQUARTERS, THE COUNCIL ON PHARMACY AND CHEMISTRY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT AND AT THE SAME TIME EXPRESSES ITS APPRECIATION OF ASSISTANCE IN PREPARING THE REPORT FROM DR. GEORGE V. S. SMITH, PROFESSOR OF GYNECOLOGY AT HARVARD UNIVERSITY.

AUSTIN E. SMITH, M.D., Secretary

THE STATUS OF TREATMENT OF VAGINITIS ASSOCIATED WITH TRICHOMONAS VAGINALIS

Hesseltine¹ has pointed out that investigators in the United States have made the major contributions of the past two decades to the subject of vaginal trichomoniasis. This evaluation of the status of treatment, therefore, is based practically entirely on the American literature, namely articles from the start of 1930 through 1942 and textbooks by American gynecologists, although foreign articles appearing during the same period have also been consulted.

PATHOGENICITY OF TRICHOMONAS VAGINALIS

Trussell and Plass² were the first to induce the disease with a bacteria free culture of the organism. Five of 9 uninfected women who were successfully inoculated developed the clinical picture of *Trichomonas vaginalis* vaginitis. The positive inoculations could not be related to the bacterial flora or the degree of acidity present in the vaginas of these women. Wolters and Hesseltine¹ confirmed this accomplishment, though they could not obtain so high a percentage of positive implantations. The fact that inoculations were not uniformly successful and that clinical manifestations of infection did not ensue in every patient harboring the implanted protozoa indicates that unknown conditions influence the pathogenicity of the flagellates. In keeping with this deduction is the absence of symptoms in 47 to 87 per cent of patients with vaginal trichomoniasis.³ The situation as regards the pathogenicity of *T. vaginalis* is summarized by Trussell and Plass: "*T. vaginalis* can produce abnormal discharge and vaginal irritation in women. These results should not be interpreted to mean that the altered bacterial flora commonly associated with the protozoa in clinical trichomonas vaginitis does not influence the extent of the

reaction, for such organisms might logically be assumed to aggravate the inflammatory process. Furthermore, it is reasonable to assume that certain vaginitides are bacterial in origin with the protozoan parasites of secondary importance." Thus in any given case of vaginitis in which the flagellates are present one may not yet be certain whether or not *T. vaginalis* is the basic pathogenic factor.

SOURCE OF INFECTION WITH *T. VAGINALIS*

The exact origin of contamination in most cases is unknown.⁴ That the mouth and rectum may be sources of infection and recurrence is accepted by a number of authors, and Karnaky⁵ believed that *Trichomonas buccalis* and *Trichomonas intestinalis* changed to *T. vaginalis* when transplanted to the vagina. Bland and Rakoff⁶ concluded that the rectum and the mouth were "improbable sources of vaginal infestation," and later attempts⁷ to infect human vaginas with *T. intestinalis* (*Trichomonas hominis*) supported their conclusion. Only 2 cases of apparent *T. vaginalis* proctitis have been reported.⁸ If *T. vaginalis* invades the rectum and thereby makes the feces a possible vector, one would expect more comment on rectal symptoms in the literature.

The lower urinary tract is considered to be one source of recurrence⁹ and the male can infrequently be the cause of infection or reinfection.¹ The glands of Skene and Bartholin may also harbor the parasites and be foci of recurrence.¹⁰

Despite the gaps in knowledge there is general agreement that vaginitis associated with *T. vaginalis* is a clinical entity.

Hesseltine,¹¹ in a 1938 report on the status of therapy, urged that, before any new procedures or preparations should be recommended, adequate and satisfactory controls should be established as regards both the disease itself and also the vehicles of the various medicaments. Since then five more substances have been added to the list of recommended agents. It is easy to understand why no significant control observations have been made. If patients are sufficiently bothered they want something done, if their symptoms are not disturbing they are not likely to be cooperative in undergoing repeated investigative manipulations. To have scientific data on the course of the disease, both mild and severe, in a series of untreated cases would indeed be most desirable.

That *T. vaginalis* vaginitis as a clinical entity may, through the working of unknown factors, be limited sooner or later in the great majority of patients is suggested by the large percentage harboring the organism without symptoms (v.s.), by the easy curability of a large percentage of those with symptoms (v.i.) and by the paucity in the literature of information concerning failures and recurrences after a three to twenty-four month period of follow-up after treatment. A disturbing amount of persistence or recurrence after two years seemingly would have excited more detailed study and comment than indicated by the following: Kahn's¹² 47 patients had had symptoms six months to four years despite various treatments. Allen, Jensen and Wood¹³ stated that 20 per cent of their patients had

variable recurrent periods of infection, some of them extending over a period of years. Mintz¹⁴ wrote that the duration of the disease varied from one week to twelve years. One of Drabkin's¹⁵ patients had been under treatment three and one-half years. The disease "may exist from months and even years without a change in its course."¹⁶

IS VAGINAL TRICHOMONIASIS POTENTIALLY DANGEROUS?

Bland, Goldstein and Wenrich¹⁷ quoted evidence from the German literature and presented their own that *T. vaginalis* increases puerperal morbidity, the criterion being a fever of 100.4 F or higher. According to Mintz,¹⁴ the organism "has been proved to be the causative factor in a few cases of puerperal morbidity." Szendi¹⁸ on the other hand, stated that the protozoan plays no role in the production of puerperal morbidity, and Moench¹⁹ sketched the course of a patient with the "worst infection with this protozoan" he had ever seen. The puerperium was normal and no organisms were demonstrable three months later. She had received no treatment.

Five of Ruble's²⁰ patients had mild pelvic inflammation while being treated, and operation showed "that type of inflammatory reaction of the pelvis which one would expect to find following gonorrheal salpingitis." Pelvic cellulitis secondary to trichomoniasis is more common than generally supposed.²¹

According to Hees,²¹ *T. vaginalis* has been found by culture and smear in the endometrium, chronically inflamed tubes, ovarian cysts, the peritoneum, the blood stream of patients and the viscera of the fetus and pelvic abscesses caused by the flagellate are not rare.

Karnaky²² discussed the presence of the organism before and after operation but made no mention of surgical morbidity, from which it may be inferred that he had none for which he held the parasite responsible. Textbooks by well known gynecologists do not lay any emphasis on possible grave complications from the flagellate. If *T. vaginalis* had serious potentialities as regards pelvic inflammation it seems that by now the evidence would be more definite than indicated by the foregoing available information.

TREATMENT

Opinion is practically unanimous that there is no specific or ideal therapy, that some patients are more difficult to cure than others and that treatment should be continued through the period of menstruation and as long as deemed necessary in pregnancy. Davis's²³ "results with all methods of treatment suggest that one may expect about 20 per cent of failures if results are judged on the basis of permanent absence of the flagellates from the vaginal secretion." According to Curtis,²⁴ "it is estimated that 85 per cent of patients obtain a clinical cure, in reality an arrest of their infection, irrespective of the treatment employed."

In the literature reviewed, the length of treatment varied from two weeks to one year, the criterion of cure was freedom from symptoms and the parasite for periods varying from two to twenty-four months after cessation of therapy and ninety substances, including vehicles, used in therapy were named, as well as acid producing bacteria, streptococcus bouillon filtrates, autogenous bacterial preparations and heat. Most methods

employed two or more up to seven, substances, not including soap and water, in combination or sequence. In the following review of reports the figures in parentheses represent the number of patients treated. Local treatment with one substance, sodium chloride (56),²⁵ quinine sulfate (39),²⁶ sodium bicarbonate (27),²⁷ picric acid (35)²⁸ and iodine (29),²⁹ was carried out in five series of cases and the results were approximately similar, viz 80 to 85 per cent of three to eight month cure, except with iodine, which gave 53 per cent.

Local treatment with the substances sodium 3-N-methanolsulfoxylic acid-amino-4-hydroxy phenylarsonic acid (Aldar one) in kaolin (100),³⁰ iodochlorohydroxy-quinoline (Vioform) in glycerin (15),³¹ p-carbamino phenyl arsonic acid (Carbarone) with sodium bicarbonate (210)³² and Vioform with magnesium trisilicate (140)³³ yielded 91 to 98 per cent of two to nine month cures.

Treatments with multiple substances involved the local use of the following various ways: picric acid, and acetylaminohydroxyphenyl arsonic acid (acetarsone) in kaolin (150),³⁴ Vioform in glycerin and lactic acid (500),³⁵ Vioform in ointment and sodium chloride (106),³⁶ sodium perborate and quinine sulfate (alone or in starch or zinc oxide) (47),³⁷ cocoa butter with oxyquinoline sulfate, picric acid and menthol, lactic acid and potassium permanganate (275),³⁸ lactic acid, lactic, citric acid and sodium bicarbonate (35),³⁹ Carbarone, sodium bicarbonate, glycerogelatin base, vinegar or lactic acid (21),⁴⁰ acetarsone, dextrose, boric acid, starch, sodium bicarbonate, tartaric acid and sodium perborate (39),⁴¹ di-iodohydroxy quinoline (Diodoquin) with dextrose, lactose and boric acid alone (100),⁴² with vinegar (4,400)⁴³ or with lactic acid (27),⁴⁴ hydrogen peroxide, and silver picrate in kaolin and in boroglycerin (20),⁴⁵ (15),⁴⁶ silver picrate in kaolin and in boroglycerin and gelatin (695),⁴⁷ (1,646),⁴⁸ silver picrate in kaolin and in cocoa butter (100),⁴⁹ (25),⁵⁰ skim milk, *Lactobacillus bulgaricus*, dextrose, lactose, liquid petrolatum starch and vinegar (50),⁵¹ and a condensation product of m-cresol sulfonic acid and formaldehyde, called negatol in powder and suppository form, and vinegar (87).⁵² The percentage of two to twenty-four month cures by these medicaments and the manner of their application ranged from 88 to 100 in all but 24 of the series of cases.

Known and unknown variables that must be operative in vaginitis include the many conceivable ways for the vagina to

become contaminated with many different organisms as well as *T. vaginalis*. The condition of the cervix and vestibular glands, the metabolic status of the pelvic organs and of the patient and the mental reactions of patients to the pelvic situation. These and variations in the technique of treatment and in the giving and carrying out of instructions (lack of cooperation is mentioned a number of times in the literature) all affect the outcome and some of these variables must have accounted for the following inconsistencies. Results of treatment with rectarsone and stovarsol (equal parts of Irohim and sodium bicarbonate with 12.5 per cent of rectarsone) have been disappointing.²³ Out of the welter of myriad treatments we have found that the simple placement of about 1.0 cc of dry stovarsol powder in the vault of the vagina every day for six treatments is infinitely superior.²⁴ Control methods were used, and it was found that apparently sodium bicarbonate by altering the pH of the vaginal secretion seemed to work as well as stovarsol so it was concluded that the latter was not necessary.²⁵ Hand and Raloff²⁶ and Meigs²⁷ had less than average good results whereas Perez Arenas and Blanchard²² had a high percentage of satisfactory results with rectarsone, there being considerable variation in technique and the use of other substances.

In this connection a number of writers emphasize the importance of general health measures. De Lee¹⁸ had 3 patients cured for five years after medication with thyroid extract orally and Moench¹⁹ had a patient whose recalcitrant *T. vaginalis* vaginitis disappeared following operation for toxic goiter.

Consideration of the foregoing adds weight to the likelihood that vaginitis like other local infections may be a limited process cure being hastened by attention to details of local and general treatment, the choice of remedies and techniques of application being matters of individual preference.

TOXICITY OF MATERIALS USED IN TREATMENT

Gellhorn²⁸ observed no local or systemic toxic effects from the vaginal insufflation of stovarsol. One case of drug rash was reported by Campbell⁹ following the vaginal application of tablets of stovarsol and Zener³¹ stated that Dr G. C. Schaeffer had had 3 cases of intolerance to a preparation of acetarsone boric acid and glycolized carbohydrates. No reactions were encountered by Peterson³⁰ in 210 patients or by Drabkin¹⁰ in 21 patients using carbarsone locally. Zener³¹ warned that silver picrate is dangerous in an alkaline medium and reported 2 cases of moderately intense local reaction therefrom as did Buxton and Shelanski.⁴¹ Kahn¹² attributed two minor complications to quinine sulfate. Angelucci²⁶ had no trouble with quinine sulfate, but 2 of her patients reacted to picric acid. Oxyquinoline sulfate produced no toxic reactions in Mintz's¹⁴ series. Capsules containing 10 Gm of sodium perborate occasionally caused chemical burns in the vagina,²¹ as did iodine in 2 instances.² It appears that the drugs covered in this review as administered were harmless in the vast majority of instances, for of 8989 patients treated only 1 experienced a drug rash and only 13 had local effects attributed to medication.

EVALUATION

The most significant aspect of the status of therapy of *Trichomonas vaginalis* vaginitis is that such good results ensue from so many substances and variations in the methods of their use and that a small percentage of failures persists in spite of similar treatment. To elucidate these failures is the chief problem. In the absence of control data, the best test of a therapy as Hesseltine¹¹ stated, would be in this small group, but perhaps these patients need something more than local treatment. Furthermore, are these cases failures of treatment to sterilize foci of organisms that cause recurrence or is the persistence of the disease due to repeated contamination? The

question cannot be answered, since both sources of contamination and foci of recurrence are obscure in nearly every patient. It is thus impossible to define complete cures except in terms of years of follow up examinations and, until more knowledge is required, no one therapeutic measure can be clearly proved superior. The status of treatment then remains a matter of personal experience with and preference for one or more of a large number of preparations.

In view of the fact that *T. vaginalis* cannot be proved pathogenic in every case of vaginitis in which it is found that unknown local and general factors are operative and that the disease is not likely to be fraught with serious possibilities and may even disappear without treatment, the present aim should be not for new medicaments but for further information, especially concerning failures. In the meanwhile thoroughness and persistence with the simplest and least messy procedures and a general health program appear to be the therapeutic objectives.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN I. SMITH, M.D., Secretary

TETANUS ANTITOXIN (See New and Nonofficial Remedies 1943, p. 526)

The following dosage form has been accepted:

PITMAN-MOORE COMPANY, INDIANAPOLIS

Tetanus Antitoxin, Pepsin Digestion Refined Vials containing 1,500 units and syringes containing 1,500 units and 10,000 units respectively. The antitoxin differs from tetanus antitoxin-U S P chiefly in the method of refinement, which is based essentially on a controlled method of selective digestion of the proteins of the immune horse blood with pepsin.

THIAMINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1943, p. 590)

The following dosage form has been accepted:

THE WARREN-TEED PRODUCTS COMPANY, COLUMBUS, OHIO
Tablets Thiamine Hydrochloride 10 mg

DIETHYLSTILBESTROL (See New and Nonofficial Remedies 1943, p. 403)

The following additional dosage forms have been accepted:

THE UPJOHN COMPANY, KALAMAZOO, MICH

Perles Diethylstilbestrol (in oil) 0.25 mg

JOHN WILEY AND BROTHER, INC., PHILADELPHIA

Tablets Diethylstilbestrol 0.25 mg

EPHEDRINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1943, p. 255)

The following dosage form has been accepted:

PITMAN-MOORE COMPANY, INDIANAPOLIS

Capsules Ephedrine Hydrochloride 24 mg (3/8 gram)

PENTOBARBITAL SODIUM (See New and Nonofficial Remedies, 1943, p. 495)

The following dosage form has been accepted:

AMERICAN PHARMACEUTICAL COMPANY, NEW YORK

Capsules Pentobarbital Sodium 0.1 Gm

THEOPHYLLINE ETHYLENEDIAMINE (See New and Nonofficial Remedies, 1943, p. 356)

The following dosage forms have been accepted:

AMERICAN PHARMACEUTICAL COMPANY, NEW YORK

Tablets Aminophylline 0.1 Gm and 0.195 Gm

THE LAKESIDE LABORATORIES, INC., MILWAUKEE

Tablets Aminophyllin 0.2 Gm enteric coated

POSTERIOR PITUITARY INJECTION (See New and Nonofficial Remedies 1943, p. 424)

The following dosage form has been accepted:

THE WARREN-TEED PRODUCTS COMPANY, COLUMBUS, OHIO

Posterior Pituitary Injection 10 cc rubber capped vials

DOES MEDICAL EDUCATION NEED TO BE REVOLUTIONIZED?

THE WAGNER-MURRAY-DINGELL BILL II

Is the rate of progress in medical education in America so slow and the stage which it has attained so inferior and the hope of further progress so hopeless as to call for a revolution? Those who have observed this progress and present attainments say emphatically "No." At the beginning of this century the American Medical Association first collected and published statistics on the medical school situation in this country.¹ In 1904 it created a permanent Council on Medical Education and began a series of annual conferences. In 1909, at the time of the fifth annual conference, only 17 schools required two or more years of college work for admission. Many medical schools were private enterprises depending on tuition for support. A large number made the payment of such tuition almost the only standards of admission, and often of graduation. In 1906 there were 162 medical colleges in the United States, many of them little more than "diploma mills."

The Council on Medical Education and Hospitals was without legal power, nor was it connected with any political or governmental agency. It achieved its results by advising and cooperating with medical schools, following thorough, impartial examination of curriculums, equipment, faculty and other requisites or essentials for teaching. Yet by 1943 the number of schools had been reduced to 76, whose standards of admission and whose quality of education were such as to place them among the foremost medical educational institutions in the world. This is still a larger number of medical schools than exists in any other two nations combined, they are graduating as many physicians as did the much larger number of inferior schools existing at the beginning of the century.

Medical education is the necessary ingredient for quality in medical practice. Only through improved

medical education comes the possibility of better and better service to the public, carrying with it reduction in morbidity and mortality and extension of the life period.

There has been progress in medical education in other countries. In no other country, however, and certainly in none with compulsory sickness insurance, has the rate of advance been so rapid or the standards reached so high as in the United States. At the beginning of the century the superiority of European medical schools caused American physicians to flock to them to complete their education. Today the tide has been reversed. Physicians throughout the world seek American medical schools as the climax of their educational career. This period during which America outstripped the former world leaders in medical education was those years in which the physicians of the lagging nations were being forced into systems of compulsory sickness insurance.

Compulsory sickness insurance in Germany put "panel doctors," or "kassenaerzte," in a class apart from private practitioners. Even the advocates of sickness insurance will scarcely claim that the titles applied to insurance physicians carry any certification of professional superiority. In other countries insurance practitioners do not have opportunities or inducements such as have led to extensive postgraduate work among general practitioners in America.

The Wagner-Murray-Dingell Bill in section 1111 proposes an entirely new method, revolutionary in almost every point, for the support and control of American medical education. The Surgeon General of the United States Public Health Service is to make "grants-in-aid" to such institutions as he thinks "show promise of making valuable contributions to the education or training of persons useful to or needed in the furnishing of medical, hospital, disability, rehabilitation, and related benefits provided under this Act or to human knowledge with respect to the cause, prevention, mitigation, or methods of diagnosis and treatment of disease and disability." Will the Surgeon General, whoever he may be, utilize the voluntary machinery set up by the medical profession and the medical schools to determine which institutions "show promise"? This bill would destroy the voluntary organization now so effectively performing this task.

Bureaucratic control of medical education will inevitably destroy the standards of excellence that now characterize the medical schools of America. Such a revolution in control could not well avoid disrupting the methods of selecting students which is essential to the preservation of the high personal qualifications and ethical integrity of the medical profession. Only a miracle could avoid temporary or permanent deterioration, if not complete destruction, of educational standards.

¹ Final Report of the Commission on Medical Education, 1932, pp 10-11

TOXIC FACTORS IN SHOCK

Until recently a substance had not been isolated from animal tissues which could be held responsible for the shock syndrome. The search for the hypothetical toxic factors in tissue has been renewed in an effort to understand the mechanisms which underlie the production of symptoms in traumatic injuries.

In 1941 Bywaters and his colleagues¹ reported myohemoglobin in the urine of injured patients. These workers suggested that this pigment may be only an indicator of muscle damage and other substances released from muscle at the same time may be responsible for the structural and functional changes in the "crush kidney."

Green,² who studied the experimental shock produced by "hind-limb ischemia" concluded that a shock producing factor is released from asphyxiated muscle. In the first attempts to obtain from normal or asphyxiated muscles an extract which on intramuscular injection would reproduce the syndrome produced by "hind-limb ischemia" the possibility developed that the hypothetical shock factor is labile and rapidly destroyed in the dying muscle. A crude saline extract obtained from muscle immediately after its removal proved to be consistently more toxic than any previously used. The factors which produce a shocklike state after intramuscular, intraperitoneal or subcutaneous injection were provisionally called muscle shock factors.

Different species of animals treated with the muscle extracts showed the cardinal features of profound depression of all vital activities with retention of consciousness almost until death, low blood volume, variable hemoconcentration, irregular fall in blood pressure, lowering of temperature, depression of renal function with anuria, nitrogen retention, albuminuria, microscopic hematuria and granular cylindruria. The administration of myohemoglobin acts synergistically with the muscle shock factors, particularly in the production of renal damage. Necropsy reveals evidences only of generalized increase in capillary permeability. The whole syndrome is remarkably similar to that seen in shock after "hind-limb ischemia." Additional similarity is shown in the development of some degree of tolerance to repeated injections of muscle shock factors as well as to the effects of repeated "hind-limb ischemia."

The experiments provide definite evidence that toxic shock producing factors were present in both normal and asphyxiated muscles. Apparently ischemia acts only by releasing normal muscle constituents into the general circulation, where they act as shock producing factors. The isolation of these factors was the next logical step. Chemical fractionation by Bielschowsky and Green³ of saline extract of acetone dried muscle

yielded a substance which analysis showed to be pure barium adenosine triphosphate. Preliminary tests with the sodium salt of this compound indicated that it possessed the full depressor and lethal potencies of the "muscle shock factors." Whether salts of adenosine triphosphate and myohemoglobin are the only toxic factors released from injured muscle is not known. It seems, however, that adenosine triphosphate alone may be responsible for the production of all the clinical features of shock. The mode of action of the substance is not understood. It seems unlikely, however, that the known metabolic actions of this compound are responsible for its shock producing properties. Acid hydrolysis of adenosine triphosphate destroying its adenosine radical did not diminish its shock producing properties. The most probable hypothesis would be that the chemical acts through the pyrophosphate part of the molecule.

Obviously these results are important in the understanding of traumatic shock in man, however, confirmation of the original work and further experimental and clinical studies are necessary before all features of traumatic shock can be explained by this mechanism.

Current Comment

DECLINE IN MATERNAL MORTALITY

Maternal mortality in the United States has decreased in the last decade by more than two thirds. The decline, according to the Statistical Bulletin of the Metropolitan Life Insurance Company for August has been from between 6 and 7 deaths per thousand live births a year to less than 2 per thousand, despite the sharply increased birth rate and the shortage of doctors and nurses. The improvement appears to be continuous, and further reduction is to be expected. The high maternal mortality prior to 1930 was due principally to inadequate care during pregnancy, confinement and the postpartum period. The gratifying results in the reduction of the loss of life of mothers and babies were accomplished primarily by the concerted effort of the medical profession and hospital managements. The medical schools have placed greater emphasis on obstetrics and have extended their postgraduate studies in this field. The hospitals have contributed much by improving their service and particularly by segregating the obstetric wards from the other services. The federal and state operated maternity and child hygiene bureaus were instrumental in arousing the interest of communities to safeguard the lives of mothers and babies. They have provided large numbers of public health nurses to render service in the homes of pregnant women and to educate them regarding approved practices of antepartum care and confinement. Various local maternity associations and many private agencies contributed much along the same lines. The sulfonamide drugs have reduced by more than a half the mortality caused by the dreaded puerperal sepsis. The mortality from this cause prior

to 1935 could not be reduced to less than 24 per thousand live births. Currently the mortality rate from this cause is reported to be less than 1 per thousand. Further progress in the reduction of the loss of life of mothers and babies, it is pointed out, can be accomplished by concentrated efforts in those areas where maternal deaths are still too frequent, namely the South and Southwest. The high maternal death rate in these areas is contributed largely by the deaths among Negro women less than half of whom are attended in their confinement by a physician.

INTERRELATIONSHIP OF ASCORBIC ACID AND THIAMINE

Four years ago Surr¹ demonstrated that rats are able to synthesize adequate amounts of ascorbic acid. The ascorbic acid content of their tissues is maintained at a normal level in spite of complete lack of ascorbic acid in the diet. This synthesis was apparently dependent on an adequate intake of certain other vitamins, prominent among them being thiamine and riboflavin. As much as 75 per cent reduction in the normal tissue concentration of ascorbic acid results from an inadequate intake of thiamine in this animal species. Dogs also normally synthesize their own vitamin C, though the relation of this synthesis to other vitamins has not yet been determined with dogs. In the course of studies of shock, Govier and his associates² of the Department of Pharmacology, Vanderbilt University School of Medicine, placed two groups of dogs on thiamine deficiency diets. One group was given the thiamine deficiency diet suggested by Goodsell³. This contains casein, sucrose, cottonseed oil, agar and cod liver oil, with autoclaved brewers' yeast to supply the other B complex vitamins. The second group of dogs was fed the thiamine deficiency diet suggested by Schaefer⁴. Instead of autoclaved brewers' yeast, the dogs on this diet were given adequate amounts of riboflavin, nicotinic acid, pantothenic acid, pyridoxine and choline by stomach tube. Many of the animals on each diet developed necrotic erosions of the buccal tissues. These began around the teeth and often became so severe as to extend almost entirely around the lower jaw. On the assumption that these necroses were only indirectly due to inadequate intake of thiamine, all dogs on the deficiency diets were given 10 mg of ascorbic acid twice weekly by stomach tube. There was a prompt healing of the oral lesions in all animals thus treated. Buccal lesions did not appear in new groups of dogs placed on thiamine deficiency diets plus ascorbic acid. The fact that ascorbic acid will prevent or cure certain secondary manifestations of thiamine deficiency in dogs is a striking extension of the known facts of vitamin interrelationships to a second animal species with suggestive bearing on problems of human nutrition.

SMALLPOX VACCINATION A REMINDER

Recently a death from tetanus followed smallpox vaccination. A careful investigation of the manufacturing records of the lot of vaccine involved and subsequent laboratory tests on this lot have failed to give any evidence that the vaccine was at fault. However, an investigation of the circumstances surrounding the vaccination and subsequent management of the case revealed that two commercially made adhesive gauze bandages containing sulfathiazole had been applied over the site of vaccination and left in place. The first symptoms of tetanus appeared on the sixteenth day following vaccination, and death rapidly ensued. This history has its counterpart in each of the 116 cases of tetanus complicating vaccination investigated by Armstrong¹ in that a dressing was attached to the arm over the vaccination. Celluloid shields and bunion pads, fortunately, have almost disappeared as vaccination dressings. It remains for the physician to renounce all dressings attached to the vaccinated arm to rid a beneficent preventive procedure of this infrequent and preventable complication. The principles of good practice in smallpox vaccination have been clearly stated by Leake². These embody the use of a properly refrigerated, potent vaccine, a small area of superficial incision of the virus just below the deltoid muscle, the avoidance of fixed dressings and careful observation of the progress of the lesion in order to determine the immunity status of the patient. In days when ready-made bandages are in every medicine cabinet there is a tendency to apply dressings to all abrasions. Admireable as such practice may be for some types of lesions, it is to be severely condemned when the fixed dressing is applied to a vaccination site. Dressings of this character tend to retain heat and moisture, thus favoring the rupture of the vesicle and the formation and retention of pus and necrotic material, ideal for anaerobic growth. Experience has shown that without such a circumstance the tetanus organism will not multiply in a vaccination wound. There is no objection to pinning a suitable dressing to the under side of a loosely fitting sleeve over the vaccinated area, particularly if the clothing is soiled.

HEALTH OF ARMED FORCES

Elsewhere in this issue (page 487) appears a detailed report released by the Office of War Information concerning the health of the armed forces of the United States. Every physician should take the time to read this report carefully so that he may participate in the pride and the glory of this magnificent record of accomplishment. Epidemic disease has been kept under control, the great menaces of previous wars have been prevented, the treatment of the wounded has been superb. And at the same time the civilian population of the United States, depleted by almost one third of the active physicians of the country, has had the lowest sickness and death rates in the history of the nation.

MEDICINE AND THE WAR

In this section of *The Journal* each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession

HEALTH OF THE ARMED SERVICES

The following release is a slight condensation of a report prepared by the Office of War Information

There have been flareups of diseases in the last eighteen months, but only cerebrospinal meningitis reached epidemic proportions and its death toll was low

The situation in units overseas is occasionally even better. In those diseases for which vaccines have been developed, it is excellent. However malaria and dysenteries present serious problems in land combat conditions and the Navy reported some trouble with infectious jaundice and with filariasis a parasitic inflammation of the glands which can produce elephantiasis

Although specific problems vary what is true of the two major branches of the armed service is in general true also of the Marine Corps the Coast Guard and of the women's services the Wacs the WAVes and the Spars

Here are some highlights of service health

1. Disease incidence was reported in 1942 lower than the preceding year and continues good in 1943. An average of a little more than 3 per cent of the Army personnel in this country was off duty because of sickness or nonbattle injuries at any given time during 1942. Abroad the rate was slightly lower, even including battle casualties. The Navy's corresponding "noneffective" rate stood at approximately 2 per cent in 1942, also a record low

2. The Army and Navy make a good report on incidence of venereal diseases among the men. Despite a policy of accepting inductees with uncomplicated cases because of the high percentage of cures possible with new treatments, the Army in the continental United States this year up to August 1 reported an average of some 40 treated annually per thousand men, and the Navy an average 33 men per thousand. If those infected before induction are eliminated from the calculation, the Army's figures stand at an all time low of 25 treated per thousand men the average for 1943 up to August 1. In this class of diseases there is a wide divergence between the major branches and the women's services. Fewer than one in ten thousand women in the uniformed services has been admitted to treatment for venereal diseases. Thanks to new types of treatments, the disability rate for these ailments is low. Of some 1,100 Wacs released for disability in a ten month period only one was discharged because of syphilis and only one because of gonorrhea

3. Cerebrospinal fever (meningococcic meningitis), which threatened to reach epidemic proportions in the early months of 1943, was controlled promptly in service posts through the use of sulfonamides to treat those infected and also in preventive dosages for those who might have had contact with the stricken man. As a consequence the peak rate of the disease lasted only a brief while and the epidemic fell off quickly. The whole pattern of the epidemic reflected the greater controls possible in military establishments as opposed to the civilian community as a whole. Deaths which in previous epidemics ran from 30 to 40 per cent of those contracting the disease were held to three to five deaths out of every hundred cases

4. The armed forces use preventive vaccines against seven key diseases: typhoid, smallpox, tetanus, typhus, yellow fever, cholera and plague. In this war there have been no cases of yellow fever in either the Army or the Navy and only a scattering of reports among the other diseases including 1 Navy case of plague. Deaths among this group of diseases were negligible. The Army reported about 60 cases of typhoid but very few deaths in 1942, the Navy 8 cases and one death in 1942

5. Dysenteries and diarrhea, including food poisoning is the Army's second greatest disease threat in number of cases among over 600 troops. The Army reports about 7 cases per thousand men in continental United States for 1942. In combat zones abroad admissions to treatment averaged about 30 men per thousand annually in 1942 and about 50 in 1943, a good record in contrast to other wars. The higher rate for 1943 was due mainly to the larger concentrations of troops in areas where these diseases have a high incidence. The sulfonamides help effect prompt cures of these ailments also

6. Malaria is a leading disease enemy overseas in land operations in malarious areas. Rates of infection in particular theaters are held secret for security reasons, but strong preventive action is being taken and the Army and Navy believe our record is superior to that of enemy forces. There are adequate supplies of essential drugs

CEREBROSPINAL MENINGITIS

In the Army camps the epidemic of cerebrospinal meningitis reached its highest rate in March 1943 when its potential was about 3 per thousand men annually. It then fell off to a low level. Currently the rate is about one tenth that of March in the entire army in continental United States. The Navy's rate for the week ended August 28 was 0.01 per thousand (1 in 100,000). The calculation used by the armed services "per thousand men per year" states the number of men per thousand who in the course of a year may be expected to be hospitalized for a given sickness if the incidence rate continues at the level noted for any special segment of a year

In civilian records both the rise and the fall of the cerebrospinal meningitis epidemic is much more gradual. It struck a high level in January of this year, rose to a crest in the week of April 17 and held close to that point for a month. In contrast to the sharp reduction of the number of cases in military establishments, the civilian epidemic decreased very slowly. In July and August, when the disease apparently was under control in armed camps, cerebrospinal meningitis was still running at five to eight times the five year median among civilians

These contrasting records are interpreted as an indication that the prompt control methods instituted by the Army were effective. Recovery from cerebrospinal meningitis has become reasonably certain, it is stated except in those cases which are classed as "fulminating" that is in which the course of the disease is so rapid, or diagnosis so delayed that sulfonamide drugs do not have time to take effect

VACCINES

Another sharp contrast between civilian and service health is shown overseas by rates of infection and mortality in those diseases for which the Army and the Navy have been provided with preventive vaccines. Incidence of these ailments among service personnel is so low that rates of infection are negligible. Inoculations used in both the Army and the Navy include typhoid, smallpox, tetanus, yellow fever, typhus, cholera and plague. Some are given to all personnel others only when there is danger of infection. In these diseases the Army reports only a few scattered cases during 1942: no yellow fever, no cholera, some 50 cases of typhus but almost no deaths, almost no smallpox or plague, practically no cases of tetanus among inoculated men. Only a few scattered deaths were reported from this entire group of diseases in the Army. The Navy reports for 1942 show 19 cases of typhus and 1 of plague with no deaths, 8 cases of typhoid with one death, no cases of any of the other diseases against which vaccines are employed

TYPHUS

Before the war's end, American soldiers undoubtedly will be fighting in areas where from 1917 to 1922 an estimated 10 million cases of typhus were reported, which resulted in approximately five million deaths. This epidemic area extends from Iran and Egypt northward through the Balkans into Poland. The global endemic area of this disease is even greater than that covered by malaria, which so far is the major disease threat in this war.

Typhus was not a problem to American soldiers in the last war because they did not fight in districts where typhus is found. This time American soldiers already have seen action in areas of infection, and the record is excellent.

Every member of our armed forces who goes into typhus zones receives three injections of typhus vaccine. Stimulating inoculations are given at intervals. This was the preparation of our soldiers who went into Egypt and North Africa.

While our forces were quartered in Egypt, there was a serious typhus epidemic among the civilian population, with an officially reported total of 32,000 cases in the first six months of 1943. There were 500 cases a week in Cairo alone during the peak of the epidemic. The death rate, as is usual with typhus, was about 30 per cent. The United States Army reported less than a score of cases and almost no deaths from typhus in the entire Middle East command during the first six months of 1943.

The vaccine used for our forces is stated to be the most effective in the world. The Germans are known to have a typhus vaccine, but it has been proved that German soldiers, on the North African front at least, are not effectively immunized, nor are the Germans believed to have the vaccine in general use as yet. Other protective measures against typhus used by the armed forces include portable live steam equipment for delousing and disinfecting clothing, which, carried in two trucks, can be shifted to various areas, fumigation delousing equipment, consisting of a synthetic rubber bag or a fumigation chamber and chemical capsules, louse repellent powders, which, applied at weekly intervals to clothing, seem to prove effective in preventing infestation of the troops. It was emphasized that typhus, unless checked, could constitute a threat to the home front also. Strenuous effort in the last war prevented importation of the louse borne strain of typhus, which is unknown in this country, although there is a weaker type of which the transmitting agent is the rat flea. To fight the disease at home and abroad, the United States of America Typhus Commission was created by an executive order of the President, Dec. 24, 1942.

Members of the commission made field examinations of soldiers to determine the effectiveness of the new control methods. They also acquired sixty-nine distinct strains of typhus from various sources and four thousand serums from typhus victims, the greatest collection ever brought together at one time. The strains came from Russia, Serbia, Syria, Palestine, Iraq, Iran, Egypt and North Africa. These samples, packed in solidified carbon dioxide and flown back from Cairo to the United States, are to be used to test the effectiveness of the present vaccine and many other studies.

According to a member of the commission, the low incidence of typhus in the United States armies under epidemic conditions is presumptive evidence of the effectiveness of our vaccine. By testing it against the various strains of the disease a definite proof can be obtained. Should the inoculation prove good only against certain strains, means can be sought to widen its efficacy. The present vaccine was developed from a strain taken in Prague in 1928. Study of the serums and strains may also make possible positive identification and diagnosis of the disease in individuals by laboratory tests.

MALARIA

Malaria constitutes a major health menace of the Army and Navy in foreign land operations in malarious areas. At home the rate is at a low level. The Army reports a rate of infection of about 0.6 men per thousand annually for this disease in 1942, or 6 men in 10,000 infected in the course of a year, and only a slightly higher rate thus far in 1943. This record is particularly good because it includes men in the continental United States who had contracted the disease in foreign areas.

It was stated on behalf of the Army that, in foreign areas, our position is better than that of other armies operating in the same theaters, and that, considering the severity of infectious conditions, our record is good. It was stressed that malaria is preventable through educating individual soldiers and officers to use constant precautions and to take full advantage of the accomplishments of science and sanitation in combating the mosquitoes which transmit the germs.

The Army's malaria rate for overseas units in 1942 was about 30 men out of a thousand, and so far in 1943 the equivalent rate is about 80. The rise this year is attributed to increased war activity in malarial areas. The number of cases of the disease in any definite locality cannot be published, according to the Army, because the enemy could use such figures to estimate the number of soldiers stationed in that area. The same explanation of security applies to specific information about many of the safeguards used by our troops in the campaign against malaria. It is stated that the Japanese failed to make adequate preparations against the fever and, as a consequence, their troops are suffering much more acutely than our own.

Security reasons explain also the lack of locality information in the Navy's statistical picture. North African bases, 1740 per thousand, outlying and "confidential" bases, 8603, fleet marine forces (landing forces), 15553 (this figure would include such troops as those who landed in Guadalcanal, where the malarial situation seems to have been as severe as in any other area), naval training stations 004, forces ashore, 1500, forces afloat, 840, entire navy, 1359.

The fight against malaria is primarily directed at destroying, or repelling, the mosquitoes which transmit the germ. The same repellents and larvicides work for all, but elimination of the mosquito vectors—those species which transmit the germs from human carriers to infect other human beings—from any given area is a much more complicated task. There are many varieties of mosquito vectors, with different breeding habits, and scarcely any two areas have the same pest to fight. For instance there is one mosquito along the Malay shores, and 20 miles inland an entirely different one. Some areas have more than one vector, one of which breeds in the shade, another in the sun. Thus, elimination of the shaded areas in which one bred would only provide large breeding areas for the other. Some breed in stagnant water, some in pools beside running water, some in brackish water. The vector in each case must be identified before its breeding areas can be attacked. The complexity of this work can be seen from the statement of Army epidemiologists that the variety in the Solomons differs from that in India, and that in turn from the vector in Burma while China has still another. Even Italy and Albania, although separated only by a narrow body of water, have different varieties of mosquito. One fact limits the danger of infection: almost all of the more numerous vectors of malaria are night feeders. In thick jungles, where there is a perpetual twilight, the mosquitoes fly throughout daylight hours also. Exclusion of such areas, however, danger of infection is generally limited to periods of night combat because of protection afforded in barracks, camps and bivouacs.

There has been made available to troops, through collaboration of the U. S. Department of Agriculture, the Army and the United States Public Health Service, a repellent which, even under strenuous combat conditions, is effective for four hours. In a bivouac its strength lasts up to six hours. This repellent, designated as Formula 612, is colorless and odorless, nonirritating and does not damage clothing, and a 2 ounce bottle contains enough for one man's use for a month. It is not an essential oil, like citronella, but a synthetic organic compound. Furthermore, a "foolproof" mosquito bar has been developed for camp and, in barracks, the much publicized "health bomb" can be depended on to destroy all insect life in a space of 1500 cubic feet. The Army previously withheld details on the contents of the "bomb" lest the enemy profit, but this prohibition is ignored by certain publications. The contents are a mixture of a chemical known as "freon," which boils at 40 degrees, combined with pyrethrum and sesame oil.

The devices which have proved so effective in home areas where the malarial rate now is almost nil, are difficult to use

in tropical or combat areas. In this country the breeding places of our particular mosquito vector, *Anopheles quadrimaculatus*, are destroyed by drainage of low lands and by the use of oil and larvicides. Present larvicides must be used at intervals of five to seven days but one is being tested which can be dusted from airplanes and which is expected to prove effective up to thirty days.

The difficulty of protecting troops against this disease lies primarily in the fact that each man must take care of himself. The devices for eliminating or foiling the mosquito vector are provided but under combat conditions men sometimes fail to use them. Consequently suppressants are administered to all troops at regular intervals. These drugs serve to keep the disease in a dormant phase. During rest periods, suppressant drugs are suspended in order to discover and treat such cases or malaria as may have been contracted. However if proper precautions are taken, suppressant drugs are not necessary. It was stated on behalf of the Surgeon General's Office. A trip by a medical commission to the highly infectious Central Africa area was cited. The medical commission used the devices made available to all the men took no drugs and returned with an absolutely clean bill of health, no malaria.

RECORDS ON HEALTH

Previous to the last war, disease regularly killed two and three times the number of men who died of combat wounds. In the last war in spite of the influenza pandemic which distorted the statistics, somewhat less than one half of all deaths were from disease or approximately the same number as were killed in action or died of combat wounds, nonbattle injuries accounting for about 4 per cent of all deaths.

Disease Incidence.—In 1942 this is reported lower in the Army than in the two preceding years and continues good in 1943, the Navy's report is largely parallel.

The Army's 'noneffective rate' showed that in 1942 an average of only 3 per cent of the men were incapacitated for duty at any given time in continental United States while in the overseas area the rate was even lower. The Navy's 'noneffective rate' stood at 2 per cent in 1942, the last year for which figures are available.

In continental United States, disease admissions to Army hospitals for 1942 were approximately 20 per cent below 1941. In respiratory diseases 1942 showed a drop of more than a fourth under 1941. During 1943 the record in both admissions from all causes and respiratory diseases is not as good as 1942 for the same period but still is better than 1941.

The Navy reports on various communicable diseases show large decreases from the levels of the last war. Lobar pneumonia killed 107 of every thousand patients in the last war but only 8 out of every thousand in 1942. Two diseases usually thought of as afflicting only children were a severe problem in the last war. Measles infected 31 out of every thousand enlisted men in 1917, 14 out of every thousand in 1918. In 1942 the rate was down to 4 per thousand. Mumps which disabled many men in the last war dropped from 40 in 1917 to 7 in 1942, a reduction of about 82 per cent. Scarlet fever is about 75 per cent as prevalent as in the last war, its death rate dropped from 272 to zero. The diphtheria death rate fell from 957 to 0.20, measles from 2283 to zero.

Venereal diseases, thanks to new treatments and more widespread education, present a vastly different aspect from that of the last war, when the Navy admissions for all venereal diseases ran 89 per thousand men in 1917 and 70.20 in 1918. In 1942 this figure had been more than sliced in half, and the rate was 33 per thousand.

The Army's rate of infection was even higher in the last war, running at over 9 per cent in 1918, over 90 men a year out of every thousand. The annual rate for 1940 in the continental United States was less than half that, approximately 40 men per thousand, and it has continued at that low level to date. The armed forces now accept inductees with uncomplicated cases of venereal diseases because of the high percentage of cures. If this group of infected inductees is eliminated from the overall figure the current figures drop to an unprecedented low rate of about 25 men out of a thousand, that is only 2.5 per cent of the personnel become infected with venereal disease, in the course of a year.

Dysenteries (including diarrheas).—These cause a large number of hospital admissions in the Army on overseas duty. There have been sporadic outbreaks at home, but through sanitary controls the rate has been held to approximately 7 per thousand men in 1942 and although the rate has gone up the record is still good so far in 1943. At the present time, dysenteries are chiefly formidable in that they incapacitate men for active duty. The sulfonamides once more do a common service here—this time it is sulfaguanidine—effecting cures of even the more severe bacillary dysenteries in five to seven days.

Overseas where under combat conditions sanitary controls are more difficult the rate is higher running about 30 men per thousand contracting the ailment in 1942. There has since been a further increase due once more to increased war activity in regions where these diseases are prevalent, and the rate thus far in 1943 has been about 50. This figure means that, out of every thousand men in overseas service during a year, 50 will be hospitalized for dysenteries if the average rate for the year thus far continues to operate.

The Navy reports a rate of 16.44 men per thousand admitted to treatment during 1942 for a group of ten selected gastroenteric disturbances including food poisoning, food infections and the dysenteries. The nine year median of these ailments is 16.30 men per thousand so that the war rate for this group is consistent with the peacetime average.

The chief work of preventing gastrointestinal infections devolves on sanitation. Water is carefully inspected and treated. Sometimes it is boiled, often filtered and chlorinated. Messes are carefully supervised, and the sanitary measures employed there are checked constantly by the medical departments. Food handlers are inspected regularly. Ashore fly control is important and inspection of animal foods under the veterinary section and of fresh vegetables by the medical division are strictly enforced. Storage of food and refrigeration also are a matter of regulations.

Despite those strenuous efforts there have been outbreaks of food poisoning and dysenteries. Laboratory tests on the causes of 169 outbreaks traced 28 of them chiefly to the Flexner dysentery bacilli and to staphylococci. At least one outbreak was attributed to 'fruity housekeeping'. In this connection it was pointed out that the methods of dishwashing used in homes would be totally inadequate in camps. Dish towels are forbidden both because of possible contamination through the cloth and because 'wiping' can cover up inadequate washing. The length of time dishes must be washed and the temperature of the water are a matter of army regulations. All dishes must be washed 'not less than forty seconds in water of 140 degrees'. This must be followed by 'immersion for thirty to sixty seconds' in water of the germ killing temperature of 180 degrees. Where thermometers are not available boiling water must be used where heating facilities are scanty, a chlorination process is required to make sure of disinfecting the dishes.

Garbage cans must be kept covered, must be cleansed daily and may not be emptied from one container to another. Instead cans are loaded on trucks, hauled to the compost and emptied there, cleansed and then returned. It is forbidden to whitewash the cans, because they might thus give a deceptive appearance of cleanliness and so might not receive a thorough scrubbing. The compost heaps are ditched and treated with oil to prevent attraction and breeding of insects. This does not affect the value of the compost fertilizer. 'It is not unusual' it was stated, 'to see such composts completely free of flies.'

OTHER DISEASES

In the last war the influenza pandemic was responsible for in the neighborhood of 800,000 admissions to hospitals and for perhaps 25,000 deaths in addition to many deaths ascribed to pneumonia but brought on as a result of influenza infection. With other respiratory diseases it caused about one third of the total admissions for disease in 1918, and roughly 80 per cent of disease deaths.

In general conditions have been better in this war. An outbreak of mild influenza started in December 1941 and carried over into early 1942 and produced relatively high admission rates. Subsequently the curve has shown only the expected seasonal variations. Practically no deaths occurred as a result of this outbreak.

One form of pneumonia, designated by the Army as "primary typical pneumonia," appeared during the last year. In March 1942 the Surgeon General called attention to the disease and so designated it. In the first month there were over 100 cases reported and the frequency increased to a peak in April 1943 of about 3,500 cases. Since then there has been some decline. Mortality is low, but the disease contributes heavily to keeping men off active duty, since lesions, demonstrable by x-ray, persist for several weeks. In the Navy, cases of atypical pneumonia ran 15 per thousand during the first six months of 1943.

Measles—Epidemic during the last war, measles has been relatively unimportant this time to either Army or Navy. In March 1941 measles reached a peak rate of almost 60 per thousand annually in the Army in the continental United States. In March, peak month in 1943, it was about 30. During the last war it was the sixth greatest cause of admissions to hospitals on account of disease, the seventh in loss of time and fourth among the diseases as cause of death. By far the larger number of deaths from measles was caused by complications, of which the most important was streptococcal bronchopneumonia.

Mumps—In the last war mumps was fourth in numerical frequency among diseases in the Army. It was third as a cause of loss of time in the Army, first cause in the Navy, and in 1918 showed the exceptionally high rate of roughly 70 per thousand annually in the Army, 35 per thousand in the Navy. It has caused but little trouble in this war. The Navy reports an incidence of 7 cases per thousand.

Tuberculosis—This disease was a costly factor in the last war. The rate for the Army was 9 men per thousand in admissions to hospitals. It caused 6 discharges for disability annually per thousand men in the Army. The death rate was about 0.7 per thousand. It was first among all reasons for dismissal from the Army, causing almost 15 per cent of the disability discharges. It was felt that tuberculosis often was present before men were admitted into the armed forces and that gas injury, rarely was an actual cause. In this war all inductees received chest x-ray examination in their preliminary examination. This is considered the best method of detecting incipient or early tuberculosis, and many men have been brought under treatment as a result of this process.

Veneral Diseases—These ranked second as a cause of admission to hospitals during the last war and second in loss of time. They present a much more hopeful picture now. Because new methods of treatment indicate a high percentage of cure, the Army now is accepting men who have uncomplicated cases of venereal diseases. Sulfonamides are used for gonorrhea, and cures run about 80 per cent in the period of ten days. Syphilis often yields to new technics within a maximum of six weeks. The Army lays stress also on improved prophylactic facilities and extensive instruction of the men in the hazards of the disease. There are periodic and surprise inspections. Recreational facilities are provided within the camps, and civilian authorities have cooperated in providing healthful entertainment in the cities.

Filaria—This tropical disease, a parasitic ailment transmitted by mosquitoes, causes some concern among naval forces. Its endemic areas cover a large part of the tropical zone of the world. The larvae of the parasitic worm are injected through the bite of the mosquito, and the life cycle of the microfilariae in the human system results in lesions and glandular swellings. Elephantiasis, or gross deformation through enlargement of certain parts of the body, has been traced to one variety of this parasite. The disease is of slow development, and the Navy and the Army are alert to avert infection of the personnel. Reports show fewer than seven cases per hundred thousand men in the Navy.

WOMEN'S AUXILIARIES

With the exception of the Wacs, the women's services keep no separate records, and their care and standards of health are incorporated in the reports of the parent services. It is stated, however, that their health problems are much the same as for the men save for venereal diseases, in which their record is much better.

The Army has prepared a statement of the causes of discharge for those Wacs released for disability. It shows that about

25 per cent were released because of ailments or defects peculiar to women and about 45 per cent for neuropsychiatric disorders. In explanation of the latter statement it is said that many of those discharged for neuropsychiatric disorders would probably not be considered as abnormal in civilian life.

Of other individual defects, arthritis caused 4 per cent of all discharges, foot defects 4 per cent and organic heart disease 2 per cent. Discharges for venereal diseases are negligible. The total number discharged for medical reasons from August 1942 to May 1943, the period covered by the report, was about 1,100.

COAST GUARD

At the present time the Coast Guard has available 1,447 beds in various infirmaries throughout the service. This number of beds is entirely independent from the facilities of either the Marine Hospitals of the Public Health Service, which currently are supplying 1,536 beds for coast guardsmen or naval hospitals. Naval hospitals admit Coast Guard patients when necessary.

The Coast Guard is operating eighteen mobile dental clinics for personnel serving at isolated stations within the continental limits of the United States. These mobile stations are equipped to operate with or without commercial electric current.

The average number of coast guardsmen ill of communicable disease admitted per week has been 500. Owing to lack of clerical help, the Coast Guard is unable to provide accurate statistics or to compute the annual rate per thousand for such conditions. At present 143 dental officers and 294 medical officers of the Public Health Service are serving full time with the Coast Guard.

DENTAL CARE

The Army has a Dental Corps of 13,000 officers, wishes to commission another 800 civilian dentists and will commission another thousand from dental schools. Those in the service now have a record of 4 million cases admitted to treatment during 1942 and more than 12½ million sittings. They installed more than seven and a half million fillings and, during the month of March 1943, extracted 582,546 teeth. In the same month they installed 456,783 dentures, and it was stated that more than half the patients treated had not been accustomed to visit dentists regularly.

Dental infection in the United States is placed at 16 per thousand men, overseas as less, 13 per thousand. Dentists have been provided with portable equipment, collapsible chair, foot powered drills and portable sterilizers for use close to combat areas. Records show that there are, under these conditions, about 250 sittings per thousand men.

The Navy has 4,000 dental officers, at least 1 assigned to every ship of cruiser class, or larger, and to every tender, hospital ship and transport. In a recent month the corps installed 50,000 fillings and restorations. Naval dentists have the same training routine as the doctors, since they may have to double for medical officers in the exigencies of combat. Their training school is at Bethesda, Md., and they may volunteer for special services such as paratroops, marine or submarine work. Those who specialize in maxillofacial surgery are sent to the Mayo Clinic for study. This work of restoring facial structure damaged in battle may include plastic surgery also and has an important place in service plans for rehabilitation of servicemen after and during the war.

HOSPITAL FACILITIES

The Army maintains about eighty general hospitals in the United States. These generally contain a thousand beds or more each. Backing up these large institutions, the department maintains hospitals of from 25 up to 1,000 or more beds, some six hundred posts, camps and stations around the country. The number of beds available in the United States for the personnel totaled about 350,000 in September with more hospitals building. In addition to these there are more than 100 established abroad. The Navy has hospital ships and hospital units which comprise 1,000 beds. The Army has hospitals, field hospital units, evacuation hospitals and stations organized right up to the front line in the continental United States. The Navy has more than 100 hospitals and seven convalescent hospitals with more than 100,000 beds, in addition to dispensaries at port and rear areas. The total of 25,000 beds.

ARMY

REHABILITATION OF THE BLIND AND HARD OF HEARING IN ARMY HOSPITALS

The War Department, Washington, D. C., recently released Circular Letter No. 16213, dealing with the rehabilitation of the blind and hard of hearing in Army hospitals, which is as follows:

STATEMENT OF FACTS

(a) Deafness and blindness are deprivations of an essential means of orientation of the normal person. The particular emotional problems of the newly blinded and deafened and their need for assistance in learning how to live without sight and hearing create a need for specialized rehabilitation.

(b) It has been established that it is essential to make an early contact with the handicapped soldier by trained personnel who can encourage him and help him to look forward hopefully to the future. Oftentimes the onset of blindness or deafness is coincident with convalescence from severe medical illness or complicating wounds which will confine a patient in the hospital for a long period of time. Early treatment which restores some of the patient's confidence and optimism will do much to shorten the rehabilitation period. It is for this reason that the program is to be started in an Army hospital instead of waiting until after the patient's discharge. It is the intention of the Medical Department to make available during the period of Army hospitalization or rehabilitation service to all who lose their eyesight or their hearing, either here or abroad. The Army does not intend to take over the entire rehabilitation program; that is the province of the Veterans' Administration for pensionable disabilities or in cases not eligible for veterans' benefits of the State Vocational Rehabilitation Services.

(c) The method of admission to a rehabilitation service of a soldier with blindness or with defective hearing to a degree which precludes the return of the patient to duty is described in a memorandum of the Adjutant General W40 14-43, 28 May 1943. This memorandum states that patients received from overseas who require specialized treatment for blindness will be classified by general hospitals receiving them and reported to the Surgeon General for transfer to the Valley Forge General Hospital, Phoenixville, Pa., or the Letterman General Hospital at San Francisco. The same procedure governs the care of the deaf who may be transferred to Dehon General Hospital, Butler, Pa., Hoff General Hospital, Santa Barbara, Calif., or Borden General Hospital at Chickasha, Okla. Patients requiring such treatment whose disability was incurred in continental United States should also be reported with a view to transfer to specialized hospitals when their physical condition does not preclude travel. The special personnel and equipment needed for rehabilitation work is not available for general use elsewhere.

THE REHABILITATION PROGRAM FOR THE BLIND

(a) It is intended that contact be made with the blind soldier at the earliest possible time by a blind worker before the psychologic aspects of the deprivation of sight may make any deep inroads on the personality. The possibility of a happy life may be best presented by one familiar with the hardships of that experience.

1 *Blind Consultant*—A blind man well adjusted to his handicap and capable of imparting that philosophy of life so essential in securing proper psychologic support has been appointed to serve in this capacity. It is intended that the consultant travel to station or general hospitals where blinded casualties are detained in advance of their being sent to the special hospital center for the blind. He is available for this service and will be advised by the Surgeon General of cases of blindness in other than special hospitals in order that he may visit them. The consultant may be expected to assist the medical staff to institute a program of rehabilitation and to arrange for local agencies to participate on a voluntary basis.

The necessity for prompt notification of the Surgeon General's Office of blinded casualties in the manner outlined in paragraph b in the statement of policy is evident.

(b) The Medical Department has placed in the hospitals designated for the care of the blind well qualified specialists in diseases of the eye and in those related conditions requiring maxillofacial and plastic surgery. Every blinded patient should have the benefit of a psychiatric consultation and an evaluation of special problems that may exist.

(c) *Education for Social Living*—1 *Ward Care and Activities*. All personnel who are to handle blinded patients should be instructed in the proper approach to the problems of the blind. Retraining in self care is essential. Avoid excesses of sympathy and don't do too much for the patient. Protect him from well intentioned untrained people who want to "do something helpful." Teach the patient to help himself. Encourage the patient to participate fully in daily physical, educational, recreational and social activities.

2 *Instruction in Special Techniques*—Trained instructors of the blind should conduct individual lessons in braille reading and writing, in typing and handwriting and in the use of other techniques and devices used by the blind. Braille can often be introduced to the patient through learning to play cards marked with symbols. Plunging a newly blinded person too suddenly into braille training is often discouraging. The occupational therapist may teach motor coordination which assists in the mastery of the environment. Ability to use one's hands and to accomplish the ordinary tasks, the development of skills, does much to give the person confidence that he is on his way once again to becoming a healthy person. The Red Cross recreational worker may encourage the patient to participate in both indoor and outdoor recreational activities and to continue normal social relationships.

(d) *The Attitude of the Family*. The social worker should assist in the very important problem of preparing the family for the reception of the blind patient in the home. An emotionally upset and oversympathetic family may, through its pity, destroy much of the self confidence and self reliance that the patient will learn unless they are prepared to meet the situation wisely. The social worker should discuss the problem with the family before they visit the patient the first time. Through their agencies the Red Cross can reach into the home and bring the interpretations necessary in every case before the patient leaves on furlough or is discharged. The social worker will also make certain that the patient is given every encouragement to continue his retraining under the direction of the Veterans' Administration and will help the patient to understand the programs and pensions available for his continued care.

(e) *Further Care of the Blind*. 1 Usually it will be possible to transfer the blinded casualty to the hospital center which has facilities and special personnel for retraining.

2 The Veterans' Administration is charged with the responsibility for rehabilitation of blindness, acquired in line of duty, and for vocational training necessary to restore the patient to a position in society where he may be reasonably self reliant if this is at all possible. Encourage every patient who is to be discharged to file an application for training with the Veterans' Administration facility located nearest his place of residence before making any other plans for after care.

THE REHABILITATION PROGRAM FOR THE DEAF

(a) *The Initial Trauma of Deafness*—It has been said that deafness offers a more severe handicap than blindness. Its disturbing effect on the personality has long been recognized. The individual feels alone, seclusive and sensitive and is very likely to feel talked about. Oftentimes he becomes preoccupied and self centered. The importance of an early contact with a hard of hearing person cannot be overemphasized, as the destructive effects on the personality can be offset by an intelligent optimism as opportunities for retraining and lip reading are made clear.

(b) *Medical Aid*—The three centers named for the care of those with impaired hearing have been staffed with experts in diseases of the ear. Special equipment for the testing of hearing and speech reception are made available in those insti-

tutions During the period of reconstructive operations and during the period of complications, speech training and lip reading are given in order that the patient may be well on the road to self sufficiency by the time he is ready to leave the hospital

(c) *Hearing Aid Policy*—Hearing aids will be furnished by the Medical Department to military personnel suffering from hearing defects, incurred in line of duty, that preclude the performance of military duty, when examination shows that such aids will materially improve the hearing of the individuals concerned and when extended hospitalization is necessary before discharge can be accomplished or it is desired to retain the individual on a duty status. The hospitals designated for the reception of patients with impaired hearing have the equipment necessary to fit hearing aids most expeditiously to the particular requirements of the individual

(d) *Education for Social Living*—1 *Ward Care and Activities* All personnel who are to handle patients with impaired hearing should be specially instructed in the procedures necessary to serve best the hard of hearing. This includes supportive care to build a feeling of security, the efforts to bring the patient into normal contacts with others and the constant awareness of the small helpful acts that help to compensate for loss of hearing. A full daily program of activities that leaves little time for self pity should be arranged

2 *Instruction in Special Techniques* A trained instructor in lip reading should conduct individual lessons. A speech teacher may also be useful to protect against the deterioration of speech. Every effort should be made to insure proper speech habits. Occupational therapy, diversional activities, entertainment and recreational facilities should be fully utilized in order that the patient may be kept in social contact with others

3 *The Attitude of the Family* As was suggested in the program for the blind, the social worker must also prepare the family for the reception of the deaf patient. The family also needs to know how to help the patient continue his training in lip reading. In all instances where the patient does not elect or is ineligible to continue rehabilitation under the provisions of the Veterans' Administration, the social worker should make certain that the patient is familiar with pension plans, state vocational rehabilitation services and the opportunities for continuation of training in his own community

(e) *Transfer to the Special Center*—In most instances it will be desirable to transfer the patient with impaired hearing to one of the three designated centers where equipment and special personnel are available. Wherever this is not possible, hospitals should take steps to secure the cooperation of local agencies for the hard of hearing within the area to provide on a voluntary basis such service until it is possible to place the patient under the care of the rehabilitation service of the designated hospital

MAJOR CHARLES R YANCEY AWARDED SILVER STAR MEDAL

According to an announcement printed in the Nashville (Tenn.) *Banner* of September 22, Major Charles R. Yancey, former Nashville physician now attached to the U S Army Medical Corps in the South Pacific, has been awarded the Silver Star Medal "for conspicuous gallantry and intrepidity in action against the enemy on Guadalcanal, British Solomon Islands, during the night of Oct 13, 1942." The citation, issued before he received his promotion, further stated that "Captain Yancey, a medical officer, was attached to a unit which was being subjected to the enemy's naval bombardment for the first time. Captain Yancey's cool judgment and personal example were responsible for keeping under control a large group of men, who through inexperience might otherwise have exposed themselves to injury. He calmly treated the wounded during the height of the bombardment. His professional skill and personal example saved many lives which might otherwise have been lost."

Major Yancey graduated from Vanderbilt University School of Medicine in 1937 and at the time of his enlistment, some two years ago, was resident surgeon at St Thomas and Protestant hospitals in Nashville

LIEUT COL SIMON WARMENHOVEN RECEIVES DISTINGUISHED SERVICE CROSS

According to the War Department, Washington, D C, Lieut Col Simon Warmenhoven, M C, U S Army, was recently awarded the Distinguished Service Cross for "extraordinary heroism in action near Soputa, New Guinea, on Nov 26, 1942. While serving as surgeon of an infantry regiment, Lieutenant Colonel Warmenhoven volunteered to accompany a group of officers on an inspection tour of the troops in the forward areas. While this party was passing through territory held by Allied troops the enemy opened fire on an Australian position with machine guns and mortars. A mortar shell exploded in the midst of a group and wounded several soldiers. With complete disregard for his own safety Lieutenant Colonel Warmenhoven went through fire lanes which were covered by enemy machine guns to the allied position and gave medical treatment to the wounded men while mortar shells were still falling in the vicinity. He remained in this exposed front line position until all the wounded had received medical aid and were evacuated. Lieutenant Colonel Warmenhoven's heroism was an inspiration to the men who witnessed it."

Lieutenant Colonel Warmenhoven graduated from Marquette University School of Medicine, Milwaukee, in 1939

BRAIN OPERATIONS PERFORMED WITH OUT DELICATE INSTRUMENTS

Capt Joseph R. Strauss, formerly of Bridgeport, Conn., according to the *Chicago Daily News*, October 12, is reported to have performed two delicate brain operations within a month, without the usual surgical instruments and without even proper sterilization of equipment, on an American quartermaster corporal and an Australian infantryman. After Japanese bombers struck the base at Tsili Tsili some time ago the Australian infantryman was found unconscious with brain tissue extruding from his right temple. He was in absolute medical shock. After giving him 250 cc of blood plasma Captain Strauss and his assistant cared for 18 other wounded men and then gave the Australian two more plasma injections. An operating table was then erected made from a stretcher covered by a brown army blanket and held up by four pronged sticks. Light came from three pulsating bulbs suspended from jungle branches and fed by a portable electric generator. Only an intravenous anesthetic was used. Captain Strauss is reported to have stated "We didn't have enough clamps, and it was cut and tie and cut and tie. We cleaned out the wound as best we could, removing dirt and shrapnel particles, and after packing the wound with sulfa we sewed it up. We put him to bed in a tent. Three of my boys stayed with him all night. They held him when he grew restless. The patient showed no temperature after three days and was sent back from the dressing station to a hospital, where he is now recovered and has all of his reflexes." Details of the other operation were not given in the item. Captain Strauss graduated from Cornell University Medical College in 1935

ARMY PERSONALS

Major Gen Norman T Kirk, Surgeon General of the Army, gave an address on "Current Plans and Policies of the Medical Department" at the Army Medical Center, September 20 before officers of the Medical Department residing in the District of Columbia and vicinity. This was the first fall meeting and officers of the Navy and U S Public Health Service also were invited. More than six hundred officers attended the meeting. Col Raymond L. Scott, M C, also addressed the group on "Experiences with an Evacuation Hospital in the African Theater."

Col Carroll D. Buck, formerly commanding officer of Fitzsimons General Hospital, Denver, was recently announced to be in charge of the Denver Medical Depot according to an announcement made by the War Department and published in the *Denver Post*. Colonel Buck, who left Denver in 1939, has been in charge of the Medical Depot at a Pacific Coast port of embarkation.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

INTERNSHIPS AND RESIDENCIES

The following letters are being sent out by the Procurement and Assignment Service for Physicians, Dentists and Veterinarians to the deans of medical schools and to hospital superintendents. When the new intern resident program takes effect on Jan 1 1944 a reshuffling of interns and residents among hospitals in the country will become necessary. At the request of the Procurement and Assignment Service and of the War Participation Committee of the American Medical Association THE JOURNAL will devote space to a record of the needs of hospitals for interns and residents and of the needs of interns and residents for places so as to enable the most rapid action possible regarding the filling of vacancies. The letters follow.

To Deans of Medical Schools —

When the new intern resident program begins Jan 1, 1944, some senior students will be unable to take internships in hospitals where they already have been accepted since the quota of interns for some hospitals will be lowered.

This means that they will have to seek internships elsewhere. There will appear in THE JOURNAL of the AMERICAN MEDICAL ASSOCIATION weekly lists of hospitals with internship vacancies.

Will you call this to the attention of those seniors whose internships have been revoked so that they may make immediate application to hospitals with vacancies?

It would be helpful also if you and your intern committee would assist these men in selecting and finding new internships. It is unfortunate that this situation exists, but the transition to the nine months internship program necessitates carrying out this procedure.

To Hospital Superintendents Accredited for Internships and Residencies —

When the new intern resident program goes into effect on Jan 1 1944 the quotas which have been established by the Procurement and Assignment Service will result in changes in the numbers of interns and residents which each hospital may retain.

Certain hospitals will be authorized more interns and residents than have been appointed. Others will have to release interns who have already signed contracts.

It is suggested that hospitals needing interns and residents to fill quotas assigned to them should submit their needs to THE JOURNAL of the AMERICAN MEDICAL ASSOCIATION for publication in the next issue. Interns and residents not now assigned to duty or relieved of assignments will then be able to communicate with the hospitals listed in THE JOURNAL who need their services.

This procedure will expedite the employment of interns and residents up to the limit of quotas assigned.

MISCELLANEOUS

FOOD RATIONING IN WARTIME

Recommendations of the National Research Council

In THE JOURNAL, October 16 (p 442), the recommendations of the Subcommittee on Medical Food Requirements of the National Research Council regarding extra rations for sick persons were published. Attention is called to the following additional recommendation of the subcommittee.

BURNS AND GASTROINTESTINAL LESIONS

Recognizing that hypoproteinemia is a frequent consequence of obstructive gastrointestinal lesions, high intestinal fistulas and severe burns and that correction of the protein deficiency may be a critical factor in promoting the recovery of patients with these conditions, the subcommittee makes the following recommendation.

Patients who have undergone operations on their stomach, intestine or colon for ulcers or cancer, those with high intestinal fistulas and those convalescing from severe burns should be allowed, per week, meat, including fish and poultry 64 ounces, milk, 7 quarts, and seven eggs. Certification in these cases should be renewed at sixty day intervals.

CORRECTION

In the previously published recommendation on Evaporated Milk and Frozen Foods for Hospitals, the following correction should be made. Amendment 116 of Ration Board No 5 should read Section 116 of General Ration Order No 5.

BRITISH HOSPITAL SHIP NEW FOUNDLAND BOMBED NEAR SALERNO

Three nurses of the Michael Reese Hospital Unit, Chicago, were awarded the Purple Heart for injuries received when the British hospital ship *New Foundland* was bombed off the Salerno beaches, September 13, according to an item in the *Chicago Daily News*, October 6. Miss Gertrude Mills of Chicago was slightly injured when fire aboard the ship caused the crew to lose control of the davits and her boat fell into the water, and two sisters from Oakland, Ill., Madonna and Agnes Nolan, who were sleeping in the same cabin when the bomb struck, had eardrum injury. Six British nurses and seventeen other persons were killed by the direct hit. Follow-

ing the bombing the ship was abandoned, and the nurses were immediately transported to Bizerte where they were refitted with clothes and equipment and prepared for another shot at Italy. Their final trip to the Salerno beachhead was made aboard an infantry landing craft which rolled and pitched throughout the two day trip. Helen Wharton of Iowa City, chief nurse of the group who managed it through its ordeal, stated. All we had to eat was K-ration and nobody ate very much of that. Fifty per cent of us were hanging on to the rails at one time or another. It was pretty bad.

SERVICE MEN ABROAD ADVISED NOT TO BRING PARROTS BACK TO THE UNITED STATES

In a recent release from the Department of the Interior, Washington, D C, Secretary of the Interior Harold L. Ickes advised that service men abroad refrain from bringing back to the United States parrots and other members of the family which may be infected with psittacosis. Birds of the parrot family include, besides parrots themselves, Amazons, Mexican double heads, African grays, cockatoos, macaws, parakeets, lovebirds, lorries, lorikeets and similar birds. Maryland, New York, Connecticut, Florida and the cities of Baltimore and Pittsburgh prohibit the importation of all species of parrots under any circumstances, they cannot be brought in even for scientific purposes. Parakeets or lovebirds may not be imported into California, Maine, Minnesota and Oregon, in addition to the other states listed. According to Talbot Denmead, in charge of the Importations and Permits Section, Fish and Wildlife Service, Chicago, it is necessary to have a federal permit for the importation of any wild bird or animal.

PRISONERS OF THE JAPANESE

According to the Cortland (N Y) *Democrat*, word had been received that Dr and Mrs Frederick Scovel and their five children will be among the prisoners of war to be exchanged with the Japanese when the exchange ship *Gripsholm* makes the next trip. Dr Scovel graduated from Cornell University Medical College New York, in 1929 and for many years has been engaged in medical missionary work in China.

ORGANIZATION SECTION

OFFICIAL NOTES

AMERICAN MEDICAL ASSOCIATION BOARD OF TRUSTEES, MEETING OF SEPT 16-17, 1943

A two day meeting of the Board was held, preceded by a full day meeting of the Executive Committee. Some of the matters acted on are reported here, others will be discussed at later meetings.

RADIO BROADCASTING

The Board authorized the resumption of the Association's broadcast "Doctors at War" on November 1, to continue for twenty-six weeks.

APPOINTMENT TO COUNCIL ON PHARMACY AND CHEMISTRY

Dr Eugene M Landis was elected to succeed Dr William C Rose (resigned) on the Council on Pharmacy and Chemistry.

COMMITTEE ON STUDENT HEALTH

The resignation of Dr A V Bock from the Committee on Student Health, because of being heavily burdened with work, was accepted.

COMMITTEE AND COUNCIL REPORTS

A report from the Council on Medical Service and Public Relations was received and placed on file as was also one from the Central Committee for Wartime Graduate Medical Meetings. The Board authorized the publication of a report of the Committee on Postwar Medical Services.

ENLARGEMENT OF ADVISORY COMMITTEE OF COOPERATIVE MEDICAL ADVERTISING BUREAU

Dr Stanley B Weld, Hartford, Conn and Dr E M Shanklin, Hammond, Ind, were elected to the Advisory Committee of the Cooperative Medical Advertising Bureau.

APPOINTMENT OF REPRESENTATIVES

Dr Victor Johnson, Secretary of the Council on Medical Education and Hospitals, was appointed to represent the American Medical Association on the Special Committee on Accrediting of the National League of Nursing Education.

Dr Morris Fishbein was appointed to serve as representative of the American Medical Association on the Joint Committee on Indexing and Abstracting of the American Library Association.

Dr Alton Ochsner, New Orleans, has been selected to represent the American Medical Association at the Primer Congreso Mexicano de Cancer Segunda Medica de Occidente to be held in Guadalajara, Jalisco, Mexico, the first week in November.

LEGISLATION

The Bureau of Legal Medicine and Legislation was instructed to call attention in its bulletin to bill H R 2985, which provides for the garnishment of wages and salaries of civil employees of the United States.

SCIENTIFIC EXHIBITS

An appropriation was made for scientific exhibits for the first quarter of the current year.

Drs Ludwig Hektoen and Urban Maes were elected to succeed themselves on the Committee on Scientific Exhibits for a period of three years.

1944 SESSION OF ASSOCIATION

The week of May 21 was selected for the next annual session of the Association, provided it is deemed propitious to hold a meeting next year.

ANNUAL CONFERENCE OF SECRETARIES AND EDITORS OF CONSTITUENT STATE MEDICAL ASSOCIATIONS

The Annual Conference of Secretaries and Editors of Constituent State Medical Associations will be held at the offices of the American Medical Association at 535 North Dearborn Street, Chicago, on Nov 19 and 20, 1943. The first session of the conference will be convened at 10 a m Friday, November 19, and an afternoon session will be held on that day. On Friday evening a program designed to be of particular interest to the editors of the constituent state medical association journals will be presented at the Palmer House. The concluding session of the conference will be held at the offices of the Association on the morning of Saturday, November 20.

It is expected that this conference will be attended by all the secretaries and editors of the constituent state medical associations, by other officers of the constituent state medical associations and by officers of component county medical societies who may wish to attend. Members of the Association will be cordially welcome.

It is important that railroad and hotel accommodations be reserved immediately.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status—A public hearing has been scheduled by the House Committee on the Judiciary on H R 786, the Tolan bill to permit chiropractors to treat the beneficiaries of the United States Employees' Compensation Act. The hearing will be before subcommittee No 2 of the Committee on the Judiciary, Nov 3, 1943, at 10 30 a m. Representative Weaver of North Carolina is chairman of the subcommittee and the other members are Representative Byrne of New York, Representative Cravens of Arkansas, Representative Reed of Illinois, Representative Towle of New Jersey and Representative Jennings of Tennessee.

H R 2976 has been reported to the House of Representatives with the recommendation that it pass, providing that during the present war and for six months thereafter the salaries of dent and all other members of the Navy Nurse Corps shall be determined under existing law to relative rank shall have the same as designated by the rank which corresponds to the relative rank heretofore provided by law for such superintendent members.

Bills Introduced—H R 3427, introduced by Representative Marrs, Minnesota provides dispensary treatment and hospitalization in Army and Navy hospitals for retired members of the Army, Navy, Marine Corps and Coast Guard.

Medical News

(PHYSICIANS WILL CONSIDER A FAVOR BY SUBMITTING
THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS
OF PRAGMATIC INTEREST SUCH AS RELATIVE TO SOCIETY ACTIVITIES
THE NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Memorial Fund for Dr. Wolfsohn—A memorial fund has been set up at the Stanford University School of Medicine to honor Dr. Julian M. Wolfsohn, clinical professor of medicine (neuropsychiatry) at Stanford who died July 1. The fund will be used by the school of medicine especially for neurology and psychiatry and will honor Dr. Wolfsohn, who had been a member of the staff since 1915. The fund was contributed by friends of the late physician.

Chiropractor and Osteopath Sentenced for "Careless Tonsillectomy"—A chiropractor and an osteopath were sentenced to two years in prison on August 17 for conspiracy to violate the medical practice act according to the Los Angeles Daily News. Their retrial on manslaughter charges was ordered by the court following the deaths of 2 children from what was described as careless tonsillectomy. Harry Navarre is the chiropractor and Leslie R. Nunn the osteopath. It is reported.

Hamilton Anderson Released by Japanese—Dr. Hamilton H. Anderson, professor and head of the department of pharmacology at Peking Union Medical College, Peking, is one of a group of persons announced by the state department is repatriated by the Japanese. The newspaper report October 14, indicated that Dr. Anderson was aboard a Japanese liner en route to Portuguese India. Prior to his joining the Peking Union Faculty, Dr. Anderson had been in charge of graduate education in the Council on Medical Education and Hospitals of the American Medical Association. Before joining the Association he had served as assistant clinical professor of pharmacology at the University of California Medical School, San Francisco.

CONNECTICUT

Vesalius Celebration—On October 30 the Yale Medical Library will present the following program to observe the 400th anniversary celebration of the publication *De Humani Corporis Fabrica*, by Vesalius.

Ernst A. Cassirer, Ph.D., New Haven: The Philosophical Character of the Science of the Renaissance.

Dr. Edward C. Streeter, Stonington: Vesalius at the University of Paris.

Carl P. Rollins, M.A., New Haven: Oporinus and the Fabricator.

Dr. Arturo Castiglioni, Baltimore: The Attraction of Puteus on Vesalius and the Defense by Cuneus.

During October the library has on display a Vesalian exhibit drawn from the collection bequeathed to Yale by the late Dr. Harvey Cushing. At the time of his death he was engaged on the compilation of a definitive bibliobibliography of Vesalius which is now in press and is being published under the auspices of the Historical Library by Mr. Henry Schuman, New York.

Psychologist Named Research Director for Public Welfare Council—Karl F. Heiser, Ph.D., director of the psychology laboratory at Norwich State Hospital, Norwich, has been appointed research director for the state public welfare council. One of Dr. Heiser's first activities will be to assist in the study of Connecticut's aged infirm and chronically ill. A committee of the Connecticut State Medical Society will participate in the study, which according to newspaper reports, is to start sometime during October. The report stated that this problem was given some attention about three years ago by a special state commission headed by Dr. Creighton Barker, New Haven executive secretary of the state society. The commission reported at that time that there was "no statistical evidence available that will permit any reasonably accurate statement of the costs to the state of those people who are 60 years of age or more who have, through state funds received hospital and medical care because of chronic illness." One of the aims of the new study is to determine whether there is a need for a separate state institution to take care of such cases. Dr. Heiser has been granted leave of absence from his state hospital position to carry on the study.

ILLINOIS

Grant for Poliomyelitis Study—The National Foundation for Infantile Paralysis has granted \$10,325 to the Illinois Committee on Infantile Paralysis to study the persistence of the virus of poliomyelitis in stools of convalescent and healthy carriers for investigation of the port of entry and exit of poliomyelitis in acute cases and for the correlation of neuropatho-

logic and clinical findings in cases of poliomyelitis during an acute outbreak. Dr. Edward A. Piszczek, Chicago, director of health of Cook County, is chairman of the Illinois Committee on Infantile Paralysis.

Conrad Sommer Heads New Mental Hygiene Section—Dr. Conrad S. Sommer, chief medical officer in the department of public welfare, has been named deputy director of the mental hygiene service, a newly created position. The new post is one of three created by the department of public welfare in a reorganization to coordinate activities. Dr. Sommer, in his new capacity of deputy director of the mental hygiene section will supervise the twelve mental hospitals, the Neuropsychiatric Institute, the division of veteran service and the bureau of home economics and nutrition. Wallace W. Clark, formerly superintendent of the division of public assistance and recently assistant regional director of the federal office of community services for the states of Wisconsin, Indiana and Illinois, has been named deputy director in charge of the section of social services covering all nonmental institutions operated by the department and also the division of child welfare, the division of services for the physically handicapped, the division of visitation of adult blind, the Institute for Juvenile Research, the division of delinquency prevention and the division of rehabilitation of women and girls.

CHICAGO

Koessler Fellowship Awarded—Maurice R. Hilleman, B.S., has received the Jessie Horton Koessler Fellowship, carrying a stipend of \$500 according to an announcement from the Institute of Medicine of Chicago. The 1943-1944 fellowship will enable Mr. Hilleman to work with Dr. Francis B. Gordon in the Ricketts Laboratory in the University of Chicago on the immunologic relations on the psittacosis like viruses.

The D. J. Davis Lectureship on Medical History—On October 15 Jens Christian Bry, librarian John Crerar Library, gave the first address under a new lectureship established by friends and colleagues of Dr. David J. Davis who retired this year as dean of the University of Illinois College of Medicine. The lecture fund was formally presented to the university on this occasion and will be known as the D. J. Davis Lectureship on Medical History. The title of the first lecture was "A Prelude to Medical History."

Personal—Everett W. Jones has been named vice president of the Modern Hospital Publishing Company effective November 1. Mr. Jones, who is head hospital consultant in the governmental division of the War Production Board and director on leave of Albany Hospital, Albany, N. Y., will for the present in his new position concentrate on problems involving the Hospital Yearbook and Latin American publications.—Raymond M. Hilliard, LL.B., executive secretary of the Illinois Aid Commission announced that his title is now public aid director.

Regional Meeting of College of Physicians—On October 16 the American College of Physicians sponsored a regional meeting at the Drake Hotel, Chicago, in conjunction with the postgraduate course in endocrinology, October 11-16 and the wartime graduate medical meeting at the United States Naval Hospital Great Lakes, Ill. October 15. The session was for the states of Illinois, Indiana, Iowa, Michigan and Wisconsin. Among the speakers were:

Lieut. Col. Ford K. Hick, M.C.A.U.S.: The Application of Graphic Training Aids to Medicine.

Dr. Robert M. Moore, Indianapolis: Effort Syndrome in Soldiers.

Capt. James E. McFarling, M.R.C.: Personal Experiences in New Caledonia with Special Reference to Malaria.

Lieut. Col. Frank Bennette Adams, M.C.A.U.S.: Some Clinical Observations on Meningococcal Infection.

Brig. Gen. David N. W. Grant, M.C.U.S. Army: Aviation Medicine.

Dr. Andrew C. Ivy, Bethesda, Md.: Recent Observations of Practical Significance on Gastric Secretion.

Dr. Fuller Albright, Boston: Classification of Hypoparathyroidism.

Dr. Ovid O. Meyer, Madison, Wis.: Some Aspects of the Diagnosis and Therapy of Hypochromic Anemias.

INDIANA

State Medical Election—Dr. Neslen K. Forster, Hammond, was chosen president-elect of the Indiana State Medical Association at its meeting in Indianapolis in September. Dr. Jacob T. Oliphant, Farmersburg, will take office as president of the association on Jan. 1, 1944. Dr. Carl H. McCaskey, Indianapolis, is now president of the association.

Division of Tuberculosis Control Created—The Indiana State Board of Health has established a tuberculosis control division to coordinate the work in the state against tuberculosis. Dr. Holland Thompson, Montgomery, Ala., director of tuberculosis control for the state of Alabama, has been named director of the new division. At present all tuberculosis control activities of the state board of health are administered by the communicable disease division.

Academy of Medicine Formed—Articles of incorporation have been issued for the Evansville Academy of Medicine, Inc., which has been organized by local physicians who are members of the Vanderburgh County Medical Society, according to the *Evansville Courier*, September 28. Dr. Stanton L. Bryan, Charles C. Suttie and Robert R. Acre have been named the incorporators. First members of the board of directors will be Drs. Keith T. Meyer, William M. Cockrum, William Lawrence Daves, Henry J. Paul, Daniel Tweedall, Pierce MacKenzie and James Y. Wolborn. The academy plans to purchase a suitable building which will house an auditorium for lecture purposes, kitchen and other facilities. There will also be offices for the academy officers and directors and a permanent secretary in addition to headquarters for the county medical society and the Evansville and district dental societies.

IOWA

New Director of Tuberculosis Control—Dr. Leon H. Flancher, epidemiologist, division of preventable diseases (tuberculosis control), Minnesota Department of Health, has been appointed director of the division of tuberculosis control of the Iowa State Department of Health. Dr. Flancher graduated at the Milwaukee Medical College in 1910.

MAINE

State Society Votes to Hold 1944 Meeting—On August 1 the council of the Maine Medical Association voted to resume the scientific session of the association in 1944. The meeting was omitted in 1943, although a meeting of the house of delegates convened. The vote of the council was taken after a return from questionnaires sent to all members of the association showed 58 per cent in favor of a return to the former custom.

MICHIGAN

State Medical Election—Dr. Andrew S. Brunk, Detroit, was chosen president-elect of the Michigan State Medical Society at its meeting in Detroit in September and Dr. Claude R. Keyport, Grayling, was installed as president. The society voted to reject the plan set up by the Children's Bureau for the care of wives and infants of enlisted men on the ground that the plan "is a clearcut case of government subsidy of the services of a doctor," newspapers reported.

Appointments for Proposed Medical Science Center—The plan to develop a \$50,000,000 medical center at Wayne University College of Medicine, Detroit, now takes shape with the announcement of definite appointments for the program. The board of trustees of the Wayne University College Hospital was incorporated on August 17. Members of the board include Mr. Alex J. Groesbeck, Mr. B. Edwin Hutchinson and Dr. A. William Lescobier chosen by the board of education of Detroit, and Mr. Wendell W. Anderson, Mr. Frederick I. Gartner and Dr. J. Milton Robb chosen by the Wayne County Board of Education. Dr. Edgar H. Norris as dean of the college of medicine is the seventh member. Dr. Frank F. Tallman, Lansing, director of mental hygiene of the Michigan State Hospital Commission, has been assigned by the commission to the board and in the development of its Industrial Health Institute and psychiatric units. The industrial institute will not be for physicians alone. It will help anybody who deals with people, it was announced, concerning itself with plant morale, human relationships within the plant, pointing the way to relate the man harmoniously with his job. One of the first units to be built by the state near Detroit will be a 2,500 bed mental hospital to serve Wayne County. The center will maintain a neuropsychiatric and a percommitment clinic in its medical hospital. The initial handling of patients will be in the outpatient department, where an attempt will be made to cure without hospitalization. George F. Pierrot, director of the United Service Organizations in Metropolitan Detroit for the past seventeen months, has been appointed executive secretary of the finance committee for the proposed medical science center. Newspapers recently reported that an appropriation of \$10,000 to initiate plans for the development of the center at Wayne University had been approved by the ways and means committee of the county board of supervisors. The selection of a site by the committee on buildings and grounds is now under consideration and will probably be decided by November 1. The plan includes a \$2,000,000 hospital and other center units, which will be operated by the Wayne University College of Medicine. Complete details have not been announced for the progress of the center, but it is hoped that this development will expand available facilities for the treatment of indigent and mental patients as well as establish a center for the study and prevention of industrial accidents and occupational diseases.

NEW HAMPSHIRE

The Mayo Lecture—The first W. J. and C. H. Mayo Memorial Lecture will be delivered at Dartmouth Medical School, Hanover, November 4, instead of November 5, according to an announcement from the university. The talk will be presented by Capt. Winchell M. Craig (MC), U. S. Naval Reserve, chief surgeon, Naval Hospital, Naval Medical Center, Bethesda, Md., on "Warriors Against Disease" (*THE JOURNAL*, October 9, p. 365).

NEW YORK

Personal—Dr. George D. Winchell, coroner of Wayne County for more than twenty years, was honored by the Wayne County Medical Association recently in recognition of his completion of fifty years in the practice of medicine.—Dr. William E. Mosher Jr., Cortland, has resigned as health commissioner of Cortland County to enter the armed services.—In August the *Albany Times-Union* named Dr. Edward F. Urba, Kinderhook, as its "hero of the month." According to the state medical journal Dr. Urba, despite the lack of proper surgical equipment, amputated the leg of an engineer trapped in a swaying locomotive during a derailment at Chatham. The presentation of a \$25 war bond is the method used by the *Times-Union* of "honoring unsung heroes on the home front."

New York City

Postgraduate Talks—Dr. Harvey B. Matthews, Brooklyn, will discuss "Causes and Management of Prolonged Labor" before the Suffolk County Medical Society, October 27. The talk is a part of the graduate instruction provided by the Medical Society of the State of New York in cooperation with the state health department. On October 21 the two groups sponsored a symposium on "Meningococcic Meningitis" before the Madison County Medical Society. Speakers were Drs. John Howard Ferguson and Abraham Clement Silverman, Syracuse.

Dr. Brill Named 1943 Salmon Lecturer—Dr. Abraham A. Brill, formerly lecturer in psychoanalysis and abnormal psychology at New York University and now lecturer in psychoanalysis and psychosexuality, Columbia University, will deliver the Salmon Lectures for 1943 at the New York Academy of Medicine, November 5, 12 and 19. Dr. Brill will speak on "The Psychoanalytic Contribution to Psychiatry." Individual topics will be "The Psychiatric Scene of 1900," "The Origin and Development of Interpretative Psychiatry" and "Freud's Specific Contributions to Knowledge of Psychosis."

Rehabilitation Clinic Opened at Lenox Hospital—On October 7 Lenox Hill Hospital opened a rehabilitation clinic to provide needed psychiatric help for men rejected at induction or discharged from the armed forces on psychiatric grounds. The clinic is similar to one established at New York Hospital and is under the direction of Dr. Thomas K. Davis with Dr. Johan H. W. van Ophuysen, attending psychiatrist, in charge. Work is being done by the neuropsychiatric staff assisted by a group of volunteer psychiatric social workers and secretaries, sessions beginning at 7:30 each Thursday evening. According to an announcement, although the therapeutic aspect will be stressed, clinical and statistical research will not be neglected as this appears to hold promise of the possible solution of post-war problems.

OHIO

Memorial for Physician—Members of the Gallia County Medical Society are sponsoring a fund for the beautification of the Gallipolis City Park as a memorial to the late Dr. George G. Kineon, medical director and superintendent of the Ohio Hospital for Epileptics. Dr. Kineon was president of the park planning commission.

Personal—Dr. Jay McLean, formerly with the Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York, has been appointed associate professor of surgical research at the Ohio State University College of Medicine, Columbus, where he will continue his work on heparin.—Dr. Edward J. McCormick has resigned as president of the Toledo Board of Health. Dr. McCormick recently moved from Toledo to the Village of Ottawa Hills, thus making him ineligible to continue on the board.

Mass Chest X-Ray Examinations—What is being called to be "the greatest mass chest x-ray examination for tuberculosis ever attempted among industrial workers in the United States" is being undertaken in Cleveland under the supervision of Dr. Joseph B. Stocklen, tuberculosis controller of Cuyahoga County, and local health commissioners and with the cooperation of the Anti-Tuberculosis League and the Cleveland Academy of Medicine. The state health department announces. The survey crew, working with a portable

speed fluorographic unit lent by the U S Public Health Service expects to visit every major war plant in Greater Cleveland. Support for the survey has been pledged by local labor organizations. X-ray examination of the chest will be given free on a voluntary basis to every plant worker. The reports will be confidential and will be given only to the worker or, on his request to his private physician. Company physicians will not have access to these reports, according to the state journal.

PENNSYLVANIA

Physician Celebrates Ninety-Fifth Birthday—Dr Joseph H Shull, physician and attorney of Stroudsburg, observed his ninety-fifth birthday on August 17. Newspapers report that Dr Shull was elected to the state senate in 1886, serving until 1890. In 1904 he went to Congress for a term. He is still in active practice.

State Medical Election—Dr William Bates, Philadelphia, was chosen president-elect of the Medical Society of the State of Pennsylvania at its meeting in Philadelphia in October. Dr Augustus S Keck, Altoona, was installed as president. Dr Walter F Donaldson, Pittsburgh, was selected secretary and Dr Henry G Munson, Philadelphia, assistant secretary.

Philadelphia

Annual Postgraduate Institute—The Philadelphia County Medical Society announces that it will hold its ninth annual Postgraduate Institute May 25, 1944. The theme of the institute will be "Modern Diagnosis and Treatment."

The Mutter Lecture—Dr Virgil H Moon, professor of pathology, Jefferson Medical College of Philadelphia, will deliver the Thomas Dent Mutter Lecture of the College of Physicians of Philadelphia, December 1. His subject will be "The Dynamics of Shock as Related to Clinical Problems." The college cooperates with the Philadelphia County Medical Society in this annual series of lectures. On November 10, Brig Gen Fred W Rankin, M R C, will lecture in this cooperative series on "Peptic Ulcer in the Army."

SOUTH CAROLINA

Changes in Health Officers—Dr Benton M Montgomery has been named director of the Clarendon County Health Department, succeeding Dr Edward Alex Heise, who is now in charge of the Sumter County and City health departments. Dr Montgomery is also director of the Williamsburg County Health Department, according to the state medical journal.

TEXAS

University News—The University of Texas Chapter of Phi Beta Pi Fraternity has given funds to the University of Texas Medical Branch, Galveston, to establish an annual lectureship. The medical school announces the publication of *Texas Reports on Biology and Medicine*, a quarterly scientific periodical available without charge to the libraries of medical institutions throughout the world.

Personal—Mr Lawrence R Payne, superintendent of the Hillcrest Memorial Hospital, Waco, has been named administrator of Baylor University Hospital, Dallas, effective October 15. Mr Payne, before taking over his Waco position, had served six years as assistant superintendent of the Baylor Hospital.—Dr Tilman E Dodd, Bryan, has resigned as health officer of the Bryan Brazos County Health Unit.—Dr John Schreiber, San Augustine, has been named health officer of Nolan County.

UTAH

Personal—Dr Rodger J B Hibbard, formerly clinician and pathologist at the Arkansas Tuberculosis Sanatorium, State Sanatorium, has been chosen superintendent of the Utah State Tuberculosis Sanatorium, Ogden, effective October 5, succeeding Dr Edward J Nagoda, resigned.

Public Health Election—E H Bramhall, BS, director of the division of laboratories of the state board of health, was chosen president-elect of the Utah Public Health Association at its annual convention, September 25, in Salt Lake City, and Dr Hyrum L Marshall, professor of physical welfare at the University of Utah School of Medicine, was inducted into the presidency.

Hospital News—Ground was broken for a five-story addition to St Mark's Hospital, Salt Lake City, September 8. The new wing will increase the number of beds by 75 and will also supply additional operating theaters and service rooms

for the entire hospital, which at present has a capacity of 225 beds. The new addition is expected to cost about \$400,000, \$100,000 of which will be paid by the hospital, the federal government providing the remainder.

WASHINGTON

Personal—Dr Cecil R Fargher, Vancouver, health officer of the Clark County Health Unit, has been named director of health of Tacoma.—Dr Claire W Twinn, acting superintendent of the Traskville State Sanatorium, Middleboro, Mass., has been appointed medical director of the King County Tuberculosis Hospital.

Spokane Medical Society Named in Affidavit—On September 11 an affidavit was filed in the superior court in Spokane charging members of the Spokane County Medical Association with agreeing not to testify against a fellow member or to cooperate in the preparation of a malpractice suit against a member. According to the Spokane *Spokesman*, the affidavit alleged that Dr Clyde W Countryman and all members of the Spokane Medical Association have agreed not to testify against a fellow member. The affidavit is on behalf of Earl H Odion and is based on the death of Mrs Helen Odion in childbirth. The action followed a defense motion for dismissal on the ground that the plaintiff failed to file a bill of particulars for a year it was stated. The suit asked damages of more than \$50,000.

WEST VIRGINIA

State Society Plans 1944 Meeting—The West Virginia State Medical Association announces that its seventy-seventh annual meeting will be held at the Hotel Windsor, Wheeling, May 15-16, 1944.

Symposium on Obstetrics—The Kanawha Medical Society was host to the sixth councilor district at a symposium on obstetrics in Daniel Boone Hotel, Charleston, October 12. Dr Harry Hudnall Ware Jr, professor of obstetrics at the Medical College of Virginia, Richmond, was the principal speaker on "Management of Breech Presentations" and "Ectopic Pregnancy."

Resolution Stipulates Granting of Temporary Licenses to Practice—On September 30 the council of the West Virginia State Medical Association adopted a resolution recommending to the public health council that it grant temporary permits from one meeting to its next succeeding meeting to such graduates from unrecognized schools as may be necessary to supply areas in which there might exist an acute shortage of doctors, such permits to be issued on the following conditions:

That actual local need be demonstrated to the complete satisfaction of the public health council.

That such graduates of an unrecognized school be given a permit to practice only as an assistant to some individual licensed physician who shall be his sponsor and who shall be responsible for all professional acts of such a graduate.

That he demonstrate to the satisfaction of the public health council his knowledge of all branches of medicine and surgery and proficiency in the use of the English language.

That such applicant for a temporary permit to practice agrees to follow and abide by such restrictions and regulations as the public health council sees proper to impose.

That in no case whatever shall such license to practice be granted or renewed for a period in excess of six months after the cessation of hostilities.

The resolution reflected the cognizance of the society that there is an insufficient number of physicians in certain communities in the state, especially in industrial areas, to provide the civilian population with adequate or necessary medical service. Indicating that it does not desire to have the standards for medical licensure set by the public health council lowered for permanent licensure in any manner whatever, the resolution and its recommendations stipulate the basis for utilizing graduates of schools not recognized by West Virginia standards for permanent licensure.

WISCONSIN

Clinic Against Whooping Cough Proposed—Dr Thaddeus D Smith, Neenah, post surgeon, was appointed as chairman of a committee to organize a clinic for immunization against whooping cough at a meeting of the Veterans of Foreign Wars, Nicolet Post 2126, Neenah, September 27.

Personal—On September 17 Acting Governor Goodland appointed Dr Erwin R Schmidt, Madison, to the Soldiers' Rehabilitation Board to succeed Col William S Middleton, MC A U S, who is on leave of absence as dean of the University of Wisconsin Medical School, Madison. Dr Schmidt is chief surgeon at the State of Wisconsin General Hospital.

GENERAL

Prizes on Endocrinology—Elizabeth L. Brown, class of 1943, New York Medical College, Flower and Fifth Avenue Hospitals, recently was presented with first prize in the Schering Award Competition for 1942 for her work on "Endocrines and the Nervous System." First prize consists of one full year's tuition. Second prize, consisting of one-half year's tuition, went to Eugene B. Brody, class of 1944, Harvard Medical School, Boston, for his paper on "Hormone Factors in Personality." Third prize of \$100 was given to Roslyn Wiener, class of 1945, University of Michigan Medical School, Ann Arbor, for work entitled "Role of Hormones in Pregnancy and Parturition." The awards were established in 1941 by the Schering Corporation for the best original papers on endocrinology.

Hospital Service Society Sued by Government—On September 17 the government filed a civil suit in district court in Washington, D. C. to declare the charter of the National Hospital Service Society, Inc., forfeited because of alleged violations of the charter terms, according to the *Washington Star*. Under the terms, it was stated, the society was to operate as a "fraternal beneficial association" for the sole benefit of its members. The government has charged the corporation has violated the charter through operating for profit and not for the sole benefit of its members, it was stated. The government also alleged the society has been governed by other than a representative form of government, contrary to the charter. It was also stated that the government had asked the court to appoint a receiver and liquidate the affairs of the corporation, in the interest of some five thousand policyholders, nearly all of whom are in the district, it was stated. The suit claims further that the society operated in Washington without a permit from the superintendent of insurance after May 1, 1940. Filed with the suit is an affidavit to show that the society was unsuccessful in court action to force the superintendent of insurance to issue it a permit after the 1940 date. The society was incorporated in Washington in August 1935, according to the suit.

Accommodations for Cardiac Patients—There are 111 institutions in the United States which accept convalescent cardiac patients, according to an announcement of a survey made by the heart division of the New York Tuberculosis and Health Association. In making the announcement Dr. J. Burns Amberson, president of the New York Tuberculosis and Health Association, said that this is the first national list of such cardiac institutions compiled and that it is considered preliminary since it is believed that there are other institutions accepting cardiac patients which the survey was unable to discover. Of the 111 known institutions, 16 are located in New York State, 2 being in New York City. Illinois stands second with 14, Pennsylvania has 12 cardiac convalescent services, while New Jersey and Massachusetts each have 9. In all there are thirty states and the District of Columbia which have 1 or more institutions for the care of cardiac patients. As a result of the survey the American Heart Association has published a directory listing each of the 111 institutions with their admission requirements, bed capacity, facilities, medical supervision, rates and staff. It lists cardiac convalescent homes for children and adults, general convalescent homes which accept cardiac patients, private schools and camps accepting cardiac patients, facilities for foster home care for cardiac children, and general convalescent homes accepting cardiac children.

The Father of American Pharmacy—The fifth painting in the "Pioneers of American Medicine" series, entitled "The Father of American Pharmacy," will be unveiled during National Pharmacy Week at a meeting in Philadelphia, November 5. The painting depicts William Procter Jr. (1817-1872) studying a formula for the standardization of drugs while at work with an assistant in his laboratory. Ivor Griffith Ph. M., president of the American Pharmaceutical Association and president of the Philadelphia College of Pharmacy and Science, will be the principal speaker at the unveiling. Ensign Melba Grafius of the Waves, stationed at Annapolis, Md., will unveil the painting. She is the fifth youngest woman graduate pharmacist in Pennsylvania, having received her degree in June 1942. The series of "Pioneers of American Medicine" is being executed by Dean Cornwell and financed by John Wyeth and Brother. Other paintings in the series which are lent to medical schools and medical societies, are "The Dawn of Abdominal Surgery," a tribute to Dr. Ephraim McDowell, depicting the world's first successful ovariectomy, "Beaumont and St. Martin" honoring Dr. William Beaumont, who pioneered in the study of the stomach's digestive functions, "Osler at Old Blockley," in honor of Sir William Osler, pioneer teacher of clinical medicine, and "Conquerors of Yellow Fever," a tribute to Drs. Walter Reed and Carlos Finlay, whose work made possible

construction of the Panama Canal, vital wartime lifeline. Procter graduated at the Philadelphia College of Pharmacy in 1837. He later served as professor there. He edited the *American Journal of Pharmacy* and founded the American Pharmaceutical Association. His chief contribution was the standardization of drugs.

United States and American Republics Exchange Medical Knowledge—Dr. Eugene P. Campbell of the health and sanitation division of the Institute of Inter-American Affairs, Washington, D. C., reports that medical men from the United States are enthusiastic about the training they are receiving in the republics to the south. Dr. Campbell is director of the United States missions assisting Costa Rica, El Salvador, Guatemala, Honduras and Nicaragua in health and sanitation programs. The training program was established by the Association of American Medical Colleges, with the financial support of the John and Mary R. Markle Foundation in New York. When the physicians arrive in Central America they report to the heads of the respective medical missions from the United States. The visiting physicians work on tropical disease cases in hospitals for three weeks. At the end of this period they go out with a field party for a week or ten days, learning more about malaria, dysentery and other tropical diseases. "This program has given our doctors experience they would not obtain elsewhere," said Dr. Campbell. "It has given them something concrete. Many doctors in the United States have had little experience with tropical medicine, and this is a handicap to the Army." Dr. Campbell said that President Tiburcio Carias Andino of Honduras has been especially interested in the program. The exchange of physicians and technicians among the Americas is an important phase of the program of inter-American cooperation which resulted from the conference of American Foreign Ministers at Rio de Janeiro in January 1942. United States physicians who have finished or are receiving training in Central America are:

Dr. Carroll C. L. Birch, assistant professor of medicine, University of Illinois School of Medicine, Chicago, assigned to Golfito, Costa Rica.
Dr. Robert C. Lowe, assistant professor of medicine, Louisiana State University School of Medicine, New Orleans, to Quepos, Costa Rica.
Dr. Walter A. Stryker, instructor of pathology, University of Michigan Medical School, Ann Arbor, to Quepos.
Dr. Eberton J. Tiffany, assistant professor of bacteriology, Long Island College of Medicine, Brooklyn, to Tela, Honduras.
Dr. George T. Harrell Jr., associate professor of preventive medicine, Bowman Gray School of Medicine, Wake Forest College, Winston-Salem, N. C., to Tela.
Dr. Roswell D. Johnson, instructor of pediatrics, Yale University School of Medicine, New Haven, Conn., to Tiquisate, Guatemala.
Dr. Robert A. Hettig, instructor of internal medicine, University of Michigan Medical School, to Tiquisate.
Dr. Lemuel W. Diggs, associate professor of medicine, University of Tennessee College of Medicine, Memphis, to Quirigua, Guatemala.
Dr. Thomas H. McGivach, associate professor of medicine, New York Medical College, Flower and Fifth Avenue Hospitals, New York, to Tela.
Dr. William McK. Germain, assistant professor of pathology, University of Cincinnati College of Medicine, to Tela.
Dr. Floyd J. Florio, associate professor of public health, University of Colorado School of Medicine, Denver, to Quepos.
Dr. Harry F. Dowling, clinical professor of medicine, George Washington University School of Medicine, Washington, D. C., to Quepos.
Dr. Myron Molnar, professor of bacteriology and immunology, Cornell University School of Medicine, Washington, to Golfito.
Dr. Russell J. Blattner, assistant professor of pediatrics, Washington University School of Medicine, St. Louis, to Tiquisate.
Dr. A. M. Fallis, demonstrator in preventive medicine, University of Toronto Faculty of Medicine, Ontario, to Tiquisate.
Dr. Wesley W. Spink, clinical associate professor of internal medicine, University of Minnesota Medical School, Minneapolis, to Quirigua.
Dr. Thomas P. Almy, instructor of medicine, Cornell University Medical College, New York, to Tela.
Dr. Carlton J. Casey, instructor of medicine, University of Virginia Department of Medicine, Charlottesville, to Tela.
Dr. Arthur L. Tritum, professor of pharmacology, University of Wisconsin Medical School, Madison, to Tiquisate.
Dr. Leslie C. Saunders, Ph.D., professor of parasitology, University of Saskatchewan School of Medical Sciences, Saskatoon, to Tiquisate.
Dr. Omar J. Fareed Jr., instructor in medicine, University of Chicago School of Medicine, to Quirigua.
Dr. Morris Tager, assistant professor of bacteriology, Yale University School of Medicine, to Quepos.
Dr. Paul A. Lembeck, instructor in medicine, University of Rochester School of Medicine and Dentistry, Rochester, N. Y., to Quirigua.
Dr. William W. Frye, associate professor of preventive medicine, public health, Vanderbilt University School of Medicine, Nashville, to Golfito.
Dr. Raymond W. Wilhelm, assistant professor of zoology, University of Missouri, Columbia, to Tiquisate.
Dr. Howard B. Shavin, assistant professor of medicine, University of Rochester School of Medicine and Dentistry, to Tiquisate.
Dr. Robert M. Shaw, professor of bacteriology, University of Alberta Faculty of Medicine, Edmonton, to Quirigua.
Dr. John W. Scott, associate professor of clinical medicine, University of Alberta Faculty of Medicine, to Tela.
Dr. Donald B. McMullen, D.Sc., assistant professor of medicine, University of Oklahoma School of Medicine, Oklahoma City, to Tela.
Dr. Francis C. Lawler, professor of medicine, University of North Dakota, Grand Forks, to Golfito.
Dr. Henry F. Wilson Jr., instructor in medicine, University College of Medicine, Chicago, to Tiquisate.

Sept 3 1943

Psychiatric Battle Casualties

The *Army Medical Department Bulletin* deals with the early recognition and treatment of psychiatric battle casualties. There is no fundamental difference between psychiatric cases arising during a battle and those occurring in civil life but the former are often more sudden and dramatic. Premontory symptoms may have been entirely lacking or under the stress of battle may have been unobserved until the breakdown occurs. They are apt to be displayed in a more vivid and spectacular form. Rapid decisions may have to be made by the medical officer in a forward area on which may depend the morale of a whole unit. Experience in the present war has shown the importance of early treatment. The incidence of psychiatric casualties depends to some extent on the nature of the action, it is likely to be higher during unsuccessful purely defensive or unduly prolonged actions. A recent analysis of all casualties evacuated from the Libyan battle area showed that 2 per cent were psychiatric and another 8 per cent were cases of physical exhaustion exhibiting transient neurotic features. The largest proportion of the psychiatric syndromes (60 or 70 per cent) were acute anxiety reactions. Hysterical reactions came next and other forms of psychosis or neurosis were of less numerical importance. It should be remembered that while the precipitating factor is the actual battle stress more complex underlying causes may be present. These may lie in the individual or his environment—either in an unstable personality or in faulty morale or discipline.

The development of symptoms may be sudden and dramatic but closer investigation will often reveal a series of changes which may have been developing over days weeks or even months. One of the earliest and most typical symptoms is a change in temperament. The quiet retiring individual becomes garrulous and vivacious or the good humored and sociable man becomes morose and sullen. Increased indulgence in alcohol or tobacco is common. Emotional instability is often manifest—sudden outbursts of weeping without apparent cause or sudden aggressiveness or even violence. Disciplinary offenses may occur in a person of previously exemplary character. There is often deterioration in the standard of work and efficiency. The individual may be irritable and jumpy unduly startled by a sudden noise. Headache and a wide variety of psychosomatic symptoms may be in evidence.

In prophylaxis, full knowledge of the men in his unit by the medical officer is important, early recognition of the premonitory symptoms may help him to avert a breakdown. Unfortunately he is often confronted with a fully developed case from another unit. Prophylaxis takes three forms. 1 Administrative. Training and discipline are of course the responsibility of the combatant officer, but the medical officer may by his advice contribute much of value to the morale of the individual and of the unit. 2 Psychologic. Listening followed by frank discussion with the individual and simple psychotherapy—explanation reassurance and suggestion—may avert an impending breakdown. 3 Psychic. Rest, adequate food and sedatives are important.

It is important to avoid indiscriminate evacuation of personnel to the rear. If a patient can be treated in a forward area the prognosis as a rule is better. But delay in evacuating men for whom specialized treatment in a base area is necessary may prove disastrous to the patient and harmful to the unit. The physically exhausted should be evacuated to a rest camp or casualty clearing station. Treatment on simple lines should

ensure return to duty in a few days. In simple terror states the great majority respond to firm handling, with a sedative and restorative hot drinks. If response is delayed, probably the condition is more serious, such as hysteria or a developing anxiety state, and evacuation for more specialized treatment is generally necessary. The main aim is to provide adequate mental and physical rest for the acute neurosis this is at least as important as for a serious physical wound.

A British Surgeon's Impression of Russian War Surgery

The visit to Russia of a party of British and American surgeons under the auspices of the Medical Research Council has been described in a previous letter to *THE JOURNAL*. One of the members the orthopaedic traumatic surgeon Mr. Watson-Jones has given his impressions of Russian war surgery in the *British Medical Journal*. The number of women doctors, women surgeons and nurses who work in the front line was remarkable. Not only do nurses attend to the wounded, but in the intervals of battle they build hospitals. They are obviously skilled in the use of the saw, the plane and the spirit level. The closed plaster technique is used for all major wounds, compound fractures and joint injuries. Professor Yudin claims that in the surgery of war this was first practiced over ninety years ago by the Russian surgeon Prokoff. Yudin teaches that after wound excision no tube or drain should be used and no gauze pad or other foreign body should be inserted. An unpadding plaster cast is applied directly over the wound. A difference from our methods practiced in Russia was of interest. A large excision of all injured and contused tissues is recommended no matter how many hours or days have elapsed since wounding and independently of the presence and degree of infection. In England it is believed that free excision is indicated only during the first twelve or possibly twenty-four hours and that after that time wide dissection is liable to disseminate infection, we think that the correct treatment in late cases is incision and drainage rather than excision and drainage. Watson Jones is still unconvinced of the superiority of the Russian method but thinks that further study is necessary.

The visitors did not approve of all they saw. They disagreed on the treatment of frostbite, they were unconvinced of the merits of muds, balsams and wood distillates. They thought that British rehabilitation was better. On the other hand, much of the Russian work was better than ours. Their specialization was excellent, their training of medical students more thorough, their organization of surgical services superb. Each of us could learn from the other.

Marriages

WILLIAM C LONG JR, Lock Haven, Pa., to Miss Geraldine E Chamberlain of High Bridge, N J, July 15

LUTHER H CONE, Chanute, Kan., to Miss Pamela Van Waaland of Sidney, Australia, June 9

CLAY R MILLER, Pensacola, Fla., to Miss Bernetta Helen Loggins in Nashville Tenn. in June

CLEMENT A SONFS to Mrs Carroll Browning Martin both of Des Moines, Iowa, September 10

PAUL F MANESS to Miss Anne Barrow, both of Jackson, N C., at Pensacola, Fla., July 28

PAUL J STRASSBURGER, New York, to Miss Dora Schurman in Cortland N Y, August 7

ROBERT PETTIBONE GILBERT Chicago to Miss Anne Henerge of Oak Park Ill., June 5

WILLIAM HOUSTON PRICE to Miss Helen Callahan both of Los Angeles, June 19

HENRY D FREEMAN to Miss Rose Specter, both of Philadelphia April 18

LOUIS A GUOCO to Miss Agatha Memoli both of Brooklyn, June 26

RECEIVED

Deaths

Leo Buerger * New York, Columbia University College of Physicians and Surgeons, New York, 1901, professor of urologic surgery at the New York Polyclinic Medical School and Hospital in 1917, formerly professor of surgery (urology) at the College of Medical Evangelists, Loma Linda and Los Angeles, member of the American Urological Association and the American Association of Pathologists and Bacteriologists, fellow of the American College of Surgeons, voluntary assistant at the Breslau Surgical Clinic in Germany, 1905-1906, for many years on the staff of Mount Sinai Hospital, attending surgeon to the Beth David and Bronx hospitals, consultant in the genitourinary department, Israel Zion Hospital, Brooklyn, and attending urologist to the Wyckoff Heights Hospital, Brooklyn, discovered Buerger's disease (thromboangitis obliterans) in 1908 and in the same year assisted in the development of the Brown-Buerger cystoscope, devised an operating cystoscope in 1910, the cystourethroscope and other urologic instruments, author of "Circulatory Disturbances of the Extremities", aged 64, died, October 6.

Henry Gray Barbour * New Haven, Conn., Johns Hopkins University School of Medicine, Baltimore, 1910, assistant professor of pharmacology at Yale University School of Medicine from 1912 to 1921, associate professor of pharmacology and toxicology from 1931 to 1937 and since 1937 research associate professor, professor of pharmacology at McGill University Faculty of Medicine, Montreal, Que., Canada, from 1921 to 1923 and professor of physiology and pharmacology at the University of Louisville (Ky.) School of Medicine from 1923 to 1931, an Associate Fellow of the American Medical Association, member of the Central Society for Clinical Research, American Physiological Society, Society of Pharmacology and Experimental Therapeutics, American Society of Biological Chemists and the Society of Experimental Biology and Medicine, conducted gas investigations for the United States government during World War I, author of "Experimental Pharmacology and Toxicology", aged 57, died, September 23, of acute pulmonary edema and hypertensive heart disease.

William Henry Lohman * Brooklyn, Columbia University College of Physicians and Surgeons, New York, 1904, professor of clinical medicine at the Long Island College of Medicine, where he had been instructor of physical diagnosis from 1908 to 1911, specialist certified by the American Board of Internal Medicine, fellow of the American College of Physicians, lieutenant in the medical corps of the U. S. Navy from 1917 to 1919, chief of the medical service, Camp Hospital number 15, American Expeditionary Forces, 1917-1918, chief of the medical service, Navy Base Hospital number 1 at Brest, France, 1918-1919, recently helped to organize Army General Hospital number 79, attending physician at the Brooklyn Thoracic Hospital from 1908 to 1910 and physician in chief from 1911 to 1916, attending physician since 1925 at the Brooklyn Hospital, assistant attending physician at St. John's Hospital from 1920 to 1930 and consulting physician since 1930, medical inspector, department of health of New York City, from 1907 to 1911, aged 62, died, August 8.

Max Joseph Exner * Newark, N. J., University Medical College of Kansas City, Mo., 1906, an Associate Fellow of the American Medical Association, epidemiologist and director of venereal disease for the city department of health, physical director for Carleton College, Northfield, Minn., from 1892 to 1898, the Y. M. C. A., in Troy, N. Y., 1898-1899, in Kansas City, Mo., from 1899 to 1908 and in China from 1908 to 1911, director of sex education for the International Committee of the Y. M. C. A., from 1911 to 1920, consultant and for many years director of the educational division of the American Social Hygiene Association, during World War I in charge of social hygiene education for the U. S. Army, cooperating with the war department commission on training camp activities, author of "Rational Sex Life for Men" and "Sexual Side of Marriage", aged 72, died in the Presbyterian Hospital, October 8.

Julian Mast Wolfsohn * San Francisco, John Hopkins University School of Medicine, Baltimore, 1911, clinical professor of medicine (neuropsychiatry), Stanford University School of Medicine, specialist certified by the American Board of Psychiatry and Neurology, Inc., member of the American Neurological Association and the American Psychiatric Association,

fellow of the American College of Physicians, served during World War I, chief medical director of the Alexander Sanitarium, Belmont, consultant in neuropsychiatry at the Children's Hospital, Mount Zion Hospital, San Francisco Hospital and the Veterans Administration Facility, member of the psychiatric board of the United States Penitentiary Hospital, Alcatraz, aged 60, died in Stanford University Hospitals July 1, following an operation for intestinal obstruction.

Louis Thales Hess * Colonel, U. S. Army, retired, Columbus, Ohio, Jefferson Medical College of Philadelphia, 1895, entered the medical corps of the U. S. Army as an assistant surgeon in 1899, rose through the various grades to that of colonel in 1918, retired in 1931 at his own request after thirty-two years' service, served for two years in Cuba during the American occupation and in 1902 was sent to the Philippines for three years, during World War I was chief of the medical service of the National Guards units in the militia bureau in Washington, D. C., for four years superintendent of the Ancon Hospital, now Gorgas Hospital, in Panama, from 1923 to 1931 was stationed at Columbus as Fifth Corps area surgeon, fellow of the American College of Surgeons, aged 72, died, July 27, of arteriosclerosis.

George Huston Bell * New York, University of Virginia Department of Medicine, Charlottesville, 1897, an Affiliate Fellow of the American Medical Association, member of the American Ophthalmological Society, past president of the New York Ophthalmological Society, fellow of the American College of Surgeons, a specialist certified by the American Board of Ophthalmology, served as eye consultant for the U. S. Public Health Service, consulting ophthalmic surgeon to the New York Eye and Ear Infirmary, consulting ophthalmologist to St. Andrew's Convalescent Hospital and the New York Polyclinic Medical School and Hospital, visiting ophthalmic surgeon to the U. S. Marine Hospital, aged 77, died, October 5, of heart disease.

Burton Alexander Hall * Oxford, N. Y., Syracuse University College of Medicine, 1907, president and for many years a member of the board of education, past president of the Chenango County Medical Society, served overseas in the medical corps of the U. S. Army during World War I, for many years served as health officer of Oxford, member of the staff of the Chenango Memorial Hospital, Norwich, consulting physician on the staff of the Woman's Relief Corps Home, member of the board of managers of Brookside Crest Sanitarium, Sherburne, a director of the National Bank of Oxford, a charter member of the Oxford Rotary Club and past president, aged 62, died, July 24, of cerebral hemorrhage and chronic cardiovascular renal disease.

Frederick Calhoun Bugbee, Tucson, Ariz., Jefferson Medical College of Philadelphia, 1925, member of the Arizona State Medical Association, diplomate of the National Board of Medical Examiners, captain in the medical reserve corps U. S. Army, not on active duty, at one time member of the Verona (N. J.) Council and served as chairman of the fire and police committees, formerly on the staffs of the Essex Mountain Sanatorium, Verona, Orange Memorial Hospital and the Montclair Community Hospital, all of New Jersey, served on the staffs of the Comstock Children's, Pinna County and St. Mary's hospitals, affiliated with the Hicks-Bugbee Church, aged 44, died, July 25, of asthma.

Ralph Kinsey Updegraff Sr., Cleveland, University of Wooster Medical Department, Cleveland, 1902, specialist certified by the American Board of Internal Medicine, past president of the Academy of Medicine of Cleveland, member of the Ohio State Medical Association and formerly councilor of the Fifth District, fellow of the American College of Physicians, formerly instructor and associate in physical diagnosis at Western Reserve University School of Medicine, director of medicine at St. John's Hospital for twenty-five years, served on the staffs of the City and St. Luke's hospitals, aged 70, died in Wilmington, Del., July 13, of coronary occlusion.

Thomas Maximus Rivers * Kissimmee, Fla., Medical College of the State of South Carolina, Charleston 1900, past president of the Midland Medical Society and the Ocala County Medical Society, served as health officer of Kissimmee and of Osceola County for many years, recently chairman of the health and housing unit under the Federal County Defense Council, member of the Southern Medical Association and the Florida Railway Surgeons Association, on the staff of the Osceola Hospital, author of "The Heart Diseases or the Rheumatic Syndrome", aged 74, died, July 2, of coronary thrombosis.

John Brest Blake, Brattleboro Vt Harvard Medical School Boston 1891, member of the Massachusetts Medical Society, American Surgical Association New England Surgical Society Boston Obstetrical Society Boston Medical Library Association and the American Gastro Intestinal Association fellow of the American College of Surgeons formerly assistant professor of surgery at his alma mater and the graduate school served for many years on the staffs of the Boston City, Long Island and Massachusetts General hospitals, Boston co author of *Case Teaching in Surgery* aged 77 died August 17 of chronic myocarditis and arteriosclerosis

George Goodhue Kineon, Gallipolis Ohio Miami Medical College, Cincinnati 1905 member of the Ohio State Medical Association American Psychiatric Association National Association for the Study of Epilepsy American Association for the Study of the Feeble Minded Eugenic Research Association and the International League Against Epilepsy chairman of the Gallia County American Red Cross and the county draft board during World War I served as judge of the Court of Honor of the Boy Scouts of America medical director and superintendent of the Ohio Hospital for Epileptics since 1911 aged 64 died August 21 of heart disease

Howard Gregory Case & Syracuse N Y Syracuse University College of Medicine 1903 associate professor of clinical surgery at his alma mater where he had been demonstrator of anatomy instructor in anatomy and applied anatomy and associate professor of surgery specialist certified by the American Board of Surgery and a member of the founders group president of the board of trustees of the Cazenovia (N Y) Seminary served on the staffs of the Syracuse Free Dispensary and the Hospital of the Good Shepherd Syracuse University where he died, August 4 of coronary thrombosis aged 62

Walter Elijah Bostwick, Algonac Mich McGill University Faculty of Medicine Montreal Que Canada 1893 served in the medical corps of the U S Army during World War I for many years served as health officer of Clay Township and as treasurer of the school board for twenty five years chairman of the Clay Township unit of the St Clair County chapter American Red Cross formerly United States deputy collector of customs for several years a member of the village council a director of the Algonac Savings Bank aged 77 died in the Harper Hospital, Detroit August 3 of pneumonia

George Hamilton Walker & Winona Minn University of Minnesota College of Medicine and Surgery Minneapolis 1908, specialist certified by the American Board of Otolaryngology member of the American Academy of Ophthalmology and Otolaryngology and the Minneapolis Otolaryngology and Ophthalmology Association fellow of the American College of Surgeons member of the Winona Clinic for many years affiliated with the Miller Clinic St Paul from 1922 to 1926, aged 63 on the staff of the Winona General Hospital where he died July 2 of cerebral hemorrhage

Edgar F Dodds & Tacoma Wash Northwestern University Medical School Chicago 1897 past president of the Pierce County Medical Society served in France and as a captain in the medical corps of the U S Army during World War I fellow of the American College of Surgeons chairman of the Tacoma Orthopedic Clinic consultant on the staff of the Northern Pacific Beneficial Association Hospital on the staffs of St Joseph's Hospital and the Tacoma General Hospital, where he died, July 23, of pernicious anemia and Hodgkin's disease, aged 71

Ray Clifton Gabler, Chambersburg Pa Hahnemann Medical College and Hospital of Philadelphia, 1932 member of the Medical Society of the State of Pennsylvania on the staff of the Chambersburg Hospital began active duty as a captain in the medical corps of the Army of the United States in November 1942 attached to the Air Corps Officers' Training School at Miami Beach, Fla relieved from active duty in June 1943 honorably discharged in July 1943 on account of physical disability, aged 39 died August 6 of a self-inflicted bullet wound

Joseph W Albright, Elizabethtown Pa University of Pennsylvania Department of Medicine Philadelphia, 1879 member and for two terms vice president of the Medical Society of the State of Pennsylvania president of the Lycoming County Medical Society in 1894 and 1901 and formerly vice president, served as president of the board of health of Muncy, formerly a member of the staff of the Muncy Valley Hospital, aged 86, died in the Philadelphia Freemasons Memorial Hospital, Masonic Homes, August 5 of chronic valvular heart disease

Clyde Rolland Bennett, Half Moon Bay, Calif., University of Nebraska College of Medicine Omaha, 1928, member of the American Psychiatric Association, aged 43, died, August 11

Gabriel D Bos & Holland, Mich Detroit College of Medicine and Surgery, 1920, on the staff of the Holland City Hospital, aged 55, died August 11, of coronary occlusion

Harry S Bossart, Buckley, Ill., Jefferson Medical College of Philadelphia 1886 also a pharmacist, for twenty-six years mayor of Buckley formerly a member of the school board for many years surgeon for the Illinois Central Railroad aged 78 died August 15, of cerebral hemorrhage

Arthur J Bradbury, Old Town, Maine University of Vermont College of Medicine, Burlington 1892 past president of the Penobscot County Medical Society served as minor and as city and school physician, aged 76, died, August 7, of heart disease

Ralph Waddell Brown, Roanoke Va University of the City of New York Medical Department, New York 1889 member of the Medical Society of Virginia, past president of the Roanoke Academy of Medicine served during World War I aged 76 served on the staff of the Jefferson Hospital where he died August 9, of heart disease

Melchor Gist Cockey, Salina, Kan University of Maryland School of Medicine Baltimore 1879 served in Cuba during the Spanish American War and in China during the Boxer rebellion formerly a captain in the Kansas National Guard aged 90 died in Kansas City, Mo, August 1 of empyema following pneumonia

Frank Smith Collier, Vicksburg Mich University of Michigan Department of Medicine and Surgery Ann Arbor, 1887 served during World War I president of the village for one term aged 79 died in a Kalamazoo hospital, August 9 of myocarditis and myocardial degeneration

William Franklin Cope, Easton Pa Jefferson Medical College of Philadelphia 1902, member of the Medical Society of the State of Pennsylvania served during World War I chief of the ophthalmology department Easton Hospital a director of the First National Bank, aged 64 died in the Cornell Medical Center New York August 17 of coronary disease

Charles Smith Craig & Hilton N Y University of Buffalo School of Medicine 1897 served as health officer of the town of Parma on the staff of the Brockport General Hospital formerly examiner for several insurance companies aged 71 died in St Mary's Hospital, Rochester, August 15 of coronary thrombosis

Norman Wilbur Currie & Plainfield N J University of the City of New York Medical Department, 1895 fellow of the American College of Surgeons served during World War I aged 71 on the staff of the Muhlenberg Hospital, where he died August 1 of heart disease and cerebral hemorrhage

Matthew Hasbrouck Du Bois, Washingtonville N Y Bellevue Hospital Medical College, New York, 1894 member of the Medical Society of the State of New York on the courtesy staffs of St Luke's Hospital, Newburgh and the Cornwall (N Y) Hospital, where he died August 8 of coronary thrombosis aged 71

Leo Huggins Du Bose, Great Falls S C University of Georgia Medical Department, Augusta 1912 also a druggist aged 55 died, August 13, of a self inflicted bullet wound

Calvin A Eaton, Yuma, Ariz Chicago Medical School 1927 member of the Arizona State Medical Association served as city health officer, aged 45 died in the Yuma County General Hospital August 2 of pulmonary embolism

Erastus Michel Finch, Takoma Park, Md National University Medical Department Washington D C 1902 also a lawyer for many years chief of the medical division of the bureau of pensions and later assistant medical referee formerly justice of the peace aged 88 died August 18 of cerebral hemorrhage, cerebral accident arteriosclerosis and hypertension

Aaron Glass, New Haven Conn St Louis College of Physicians and Surgeons and the Kansas City College of Medicine and Surgery 1922 aged 54 died suddenly August 2

William Emmett Ham, Beattie Kan Rush Medical College Chicago 1882 member of the Kansas Medical Society served as mayor councilman member of the school board of district number 29 and postmaster aged 85 died in the Randell Hospital, Marysville July 30

Clara Addleman Hooper, Glen Arbor Mich Bennett Medical College Chicago 1913 aged 73 died in the James Decker Munson Hospital Traverse City July 26, of cerebral hemorrhage

Everett Dennison Hooper, Boston College of Physicians and Surgeons, Boston 1891, aged 74 died, June 1

Y Frank Hopkins * Taylor, Texas, Kentucky School of Medicine, Louisville, 1901, served during World War I, on the staff of the Wedemeyer Hospital served as president and director of the Kiwanis Club, aged 66, died, July 19, of carcinoma of the colon

Maximilian R Horwitz, St Louis, Missouri Medical College, St Louis, 1893, formerly on the staff of the Missouri Baptist Hospital, aged 72, died, July 29, of heart disease

Thomas L Howard, Augusta, Ga, University of Georgia Medical Department, Augusta 1908, also a pharmacist, at one time trustee from the 119th district, aged 64, died, July 28, of heart disease

George Frederick Hughes Jr, Somerville, Mass Tufts College Medical School, Boston, 1900, aged 71, died, June 3, of cerebral hemorrhage with hypostatic pneumonia

Herbert Wellington Insley, Chanute, Kan, University Medical College of Kansas City, Mo, 1913, member of the Kansas Medical Society, served in France during World War I aged 61, died, July 16

Alton Atwell Jackson, Everett, Mass, Harvard Medical School, Boston, 1883, member of the Massachusetts Medical Society, member of the Selective Service Board during World War I on the staff of the Whidden Memorial Hospital, aged 89, died, July 26, of pneumonia

Charles Albert Jenkins, Willimantic Conn, Baltimore Medical College, 1911, member of the Connecticut State Medical Society, served as health officer of Willimantic, served in France during World War I, at one time trustee of the Norwich State Hospital, aged 55, died in the Windham Community Memorial Hospital, July 24

Edgar Augustus Jones, Avant, Okla, Vanderbilt University School of Medicine, Nashville, Tenn, 1885, member of the Oklahoma State Medical Association, served during World War I, aged 82, died in the Veterans Administration Facility, Muskogee, July 15, of cerebral hemorrhage

William Frederick Kaiser * Portland, Ore, University of Oregon Medical School, Portland, 1908, recently on the staff of the Portland induction center, aged 63, died in the Providence Hospital, July 8

George L Kearney, St Louis, Missouri Medical College, St Louis, 1891, formerly on the staff of the City Sanitarium, aged 79, died, August 5, of myocarditis

William R Kennedy, Wauwatosa, Wis, State University of Iowa College of Homeopathic Medicine, Iowa City, 1895, member of the State Medical Society of Wisconsin, on the staff of St Luke's Hospital, Milwaukee, aged 71, died in St Mary's Hospital, Milwaukee, August 3, of diverticulosis of the colon

John Francis Kent, Brooklyn, Bellevue Hospital Medical College, New York, 1888, member of the Medical Society of the State of New York, served as medical inspector of schools for the department of health, aged 78, died in the Kings County Hospital, August 1, of arteriosclerosis and papilloma of the bladder

Ralph Porter Kent * Attleboro, Mass, Harvard Medical School, Boston, 1904, served as health officer of Attleboro, member of the staff of the Sturdy Memorial Hospital, aged 63, died in Oak Bluffs, August 4, of cerebral hemorrhage

James Silas Kolb, Clarksville, Ark, University of Arkansas School of Medicine, Little Rock, 1892, member of the Arkansas Medical Society, past president of the Johnson County Medical Society on the staff of St Hildegard's Municipal Hospital, aged 78, died, August 9, of thromboangitis obliterans of the left leg

Siegfried Kraft * Sheboygan, Wis, Leopold-Franzens-Universität Medizinische Fakultät, Innsbruck, Austria 1909, member of the staff of the Sheboygan Memorial Hospital dermatologist and urologist to the Sheboygan Clinic, aged 60, died, August 3, of bronchiogenic carcinoma of the lung

John William Krohn * Joliet, Ill, the Hahnemann Medical College and Hospital, Chicago, 1912, fellow of the American College of Surgeons, formerly state surgeon, served in France

during World War I, member of the Selective Service System, on the staff of St Joseph's Hospital, active executive chairman and formerly chief of staff at the Silver Cross Hospital, where he died, August 21, of lobar pneumonia and coronary thrombosis, aged 52

Bernard John Lammers, Louisville, Ky, Louisville Medical College, 1890, aged 81, served on the staff of St Anthony's Hospital, where he died, August 2, of pernicious anemia and myocarditis

Nicholson Chambers Lanier, New Orleans, Medical Department of Tulane University of Louisiana, New Orleans, 1895, aged 77, died in the Charity Hospital, July 18, of malnutrition and anemia

David William Medill, Martins Ferry, Ohio, Colorado School of Medicine, Boulder, 1896, also a pharmacist, aged 71, died, July 28

Amherst Merriman, La Jolla, Calif, Detroit College of Medicine and Surgery, 1921, member of the Colorado State Medical Society, aged 46, died in Ramona, July 30, of acromegaly

Marion Lexter Montgomery, Louisville, Miss, Mississippi Medical College, Meridian, 1910, member of the Mississippi State Medical Association health officer of Winston County, member of the Rotary Club, aged 61, died in Memphis, Tenn, August 10, of coronary heart disease

Albert Augustus Parker * Pocomoke City, Md, College of Physicians and Surgeons, Baltimore, 1909, a charter member and first president of the Rotary Club of Pocomoke City, aged 58, died in Dr Harvey Beck's Clinic, Baltimore, August 3, of coronary thrombosis

James Haven Pond, Los Gatos, Calif, Oakland College of Medicine and Surgery, 1910, a director of the First National Bank of Los Gatos, aged 80, died, August 6, of arteriosclerotic heart disease and coronary occlusion

Albert Alexander Potterf, Leavenworth, Kan, Homeopathic Medical College of Missouri, St Louis, 1888, aged 91, died, July 16, of lobar pneumonia

Ira W Robertson, Tulsa, Okla, Memphis (Tenn) Hospital Medical College, 1901, formerly owner of a hospital in Henryetta, aged 74, died, July 30

John Ansel Schoonover * Denver, University of Cincinnati College of Medicine, 1925, assistant professor of pediatrics at the University of Colorado School of Medicine, specialist certified by the American Board of Pediatrics, Inc, member of the American Academy of Pediatrics, served as president of the medical staff of the Children's Hospital, where he died

July 13, of uremia, polycystic kidneys and a fractured scapula, aged 43

Thomas Campbell Sexton, Fremont, Neb, Washington University School of Medicine, Baltimore, 1871, Civil War veteran, aged 99, died, July 28, of coronary thrombosis

Alfred Joy Willits, Anaconda, Mont, Northwestern University Medical School, Chicago, 1900, member of the Medical Association of Montana, fellow of the American College of Surgeons, clinical assistant in medicine from 1908 to 1912 and clinical assistant in surgery at his alma mater from 1912 to 1914, for twenty-three years chief of staff of St Ann's Hospital, aged 68, died, July 26, of heart disease

KILLED IN ACTION

Edward Ellsworth Evans * Surgeon 1st Class, Commander U S Navy, San Francisco University of Oregon Medical School, Portland 1922, entered the U S Navy in June 1928 as an assistant surgeon 1st junior grade, Evans Avenue on the recruitment of the U S Naval Hospital Dublin Ga named in 1943, the Bureau of Medicine and Surgery, aged 43, in action in the Solomon Island Dec 12, 1942

EVALUATION OF ALBUMINURIA

To the Editor—In THE JOURNAL, August 14, page 1151, a clinical pathologist for an army induction team described his difficulties in knowing when to reject a man with albuminuria. At one army induction station during the course of a study (to be published) on several aspects of albuminuria in March and April 1943 we formulated a series of rules to aid the examining physicians in evaluating the albuminuria cases. We have found them to be applicable to practically all questions regarding the significance of albuminuria that arise in connection with the processing of large numbers of men in a short period of time.

DIRECTIONS FOR DETERMINING SIGNIFICANCE OF ALBUMINURIA IN SELECTEE

1 All albuminuria cases except (a) those definitely rejected on other grounds and (b) those whose albuminuria clears with the second test, are studied by a special method.

2 When albumin is found in the first two urines the selectee is given a printed form by the laboratory with orders to return as soon as possible for additional urine examinations. He is also advised to restrict the intake of fluids.

3 On his return the selectee assumes the prone position on an examining table in one of the cubicles. A urine is collected at the end of half an hour and at the end of one and one-half hours, these samples are voided while the selectee is still in the recumbent position.

4 The results of the urine examinations are recorded by the laboratory on a special form which is then attached to the record of the selectee. On this special form are written

Name	Date	
Urine No	Albumin	Initials
1		
2		
3		

After ½ hour recumbency

After 1½ hours recumbency

If rejected state diagnosis

This slip is to be kept by the Medical Officer

INTERPRETATION OF RESULTS OF URINE TESTS

5 If the last two or more urines are negative for albumin, the case is one of transient albuminuria and the man should be accepted.

6 If the last urine (which is the second voided in the recumbent position) is negative for albumin the case is one of orthostatic albuminuria and the man should be accepted if no more than a rare cast or red or white cell is found on only one of several observations.

7 If albumin persists in all urines, the following inquiries should be made:

- Presence of urinary symptoms (such as frequency, nocturia, hematuria, pyuria and pain)
- Previous rejections here
- History of albuminuria or edema
- Previous diagnosis of kidney disease
- Upper respiratory infections (present or very recent)
- Moderate intake of alcohol previously
- Sexual intercourse or masturbation the night before examination
- History of gonorrhea

8 If a definite diagnosis of chronic kidney disease can be made on the basis of answers to the questions, the persistence of albuminuria and the findings in the sediment, the man should be rejected.

9 If a definite diagnosis cannot be made, the man should be deferred for two months. At that time urines will be examined again and a final decision made, unless a factor that may produce temporary albuminuria (such as colds or alcoholism) is present, in which case the selectee should again be deferred. If there is no such factor, and the albuminuria is persistent, then the man should be rejected on the basis of persistent albuminuria.

10 All pertinent information obtained in section 7 should be recorded on the back of the work sheet.

The terms transient orthostatic or persistent albuminuria are used to describe the several varieties encountered. Men who show persistent albuminuria should be rejected because they are the ones with overt or insidious renal disease (Derow, H. A. The Diagnostic Value of Serial Measurements of Albuminuria in Ambulatory Patients *New England J Med* 227: 827 [Nov. 26] 1942; Young H. H., Haines, J. S., and Prince, C. I. Orthostatic Albuminuria: The Importance of Its Recognition by Medical Examining Boards, *U.S. Surgeon* 92: 353 [April] 1943).

WOUND HEALING AND IMPLANTATION OF SULFONAMIDES

To the Editor—In the August 7 issue of THE JOURNAL in the article on 'Wound Healing and Infection After Local Implantation of Sulfonamide Powder' by J. Albert Key, mention is made of an earlier paper of mine. I believe it would be well if I answered certain of the observations.

Late in 1942 I published further observations in the *Journal of Bone and Joint Surgery* in which I pointed out that, among other things, larger amounts of sulfonamides were used topically in the earlier months than were necessary and that after the publication of my first report I began using smaller quantities. However, I feel that the larger amounts were not the only retarding factor in wound healing, that the application of the drug to the cutaneous edges of the wound was, if anything, more disadvantageous. Since my first publication I have used sulfanilamide topically in well over 400 cases of all types—clean, infected, lacerated and other traumatic wounds, and in surgical incisions. I am fully convinced, as I have been from the start of its protective and therapeutic effects. But I place it deep in the wound, and if I do place it subcutaneously I keep it away from the skin edges. By attending to these two factors, distribution and quantity I believe I have avoided any retardation of healing. May I add that the quantities used previous to my first report, and on which that report was based, were the quantities currently used at that time. If my memory serves me right, and I do not have any reference material at hand, Dr. Key shortly after that publication, or at about that time, was advocating lesser quantities of the drug than had been used.

The material which I am now seeing at rather close quarters has increased my belief in the efficiency of sulfonamides used topically. I am not yet ready to publish any data because I use it on all casualties since my faith in it forbids me to withhold it from any. Since my later publication (*J. Bone & Joint Surg.* 24: 937 [Oct.] 1942) has already noted these changes it would be too bad if an earlier observation in any way dissuaded surgeons from its use. I believe that even there I stated that its use had become obligatory in any case of potential infection.

MEDICOLEGAL ABSTRACTS

Medical Practice Acts Failure of Physician to Appeal from Order Revoking License as Affecting Right to Equitable Relief—The plaintiff was licensed in 1912 to practice medicine and surgery in the state of Washington. She was convicted in November 1938 of violating the federal narcotic act and was sentenced to imprisonment in a penal institution in Minnesota. In January 1939 a complaint was filed with the director of licenses of Washington, alleging that because of the facts on which the conviction was had the plaintiff was guilty of unprofessional conduct and asking that her license "to practice drugless healing" be revoked. Notice of this complaint and of the hearing to be held on it was served on her in the penal institution out of the state of Washington. On February 23, while the plaintiff was still confined in the penal institution, a hearing was held in Washington on the complaint and at that hearing she was represented by counsel. Following the hearing, the director revoked her license "to practice medicine and surgery," Aug 4, 1939. No appeal was taken from either the federal conviction or the order revoking her license. In February 1941, more than a year subsequent to the revocation of her license, she filed a motion with the state director of licenses to vacate the order of Aug 4, 1939, alleging that that order was unlawful and void because it revoked her license to practice medicine and surgery, a judgment in excess of the relief asked for in the unamended complaint filed with the director, which sought merely to revoke her license "to practice drugless healing." The director overruled the motion, and the plaintiff instituted an action in equity to set aside the director's order revoking her license. The trial court dismissed the action, and the plaintiff appealed to the Supreme Court of Washington.

The plaintiff contended that the trial court erred in dismissing her action because, (1) in view of the fact that she was confined out of the state when the notice of the hearing was served on her, the notice was insufficient in form and (2) the action of the trial court was based on certain "interdepartmental evidence of which she had no knowledge or opportunity to rebut." A sufficient answer to these contentions, said the

Supreme Court, is the fact that the plaintiff was at all times represented by counsel. This remark of the court impliedly indicated that all defects, if any, in the proceedings before the director were waived by the appearance of counsel. Apparently, it was then suggested that the attorney who appeared for the plaintiff at the hearing and in filing the motion with the director to vacate the order of revocation had merely appeared specially. In effect, this contention was that the counsel had appeared solely to question the jurisdiction of the director to proceed under the circumstances and not to defend the action on its merits and hence his appearance did not waive defects in the complaint and in the proceedings that followed. However, the court was unable to find anything in the record that would indicate that counsel had appeared specially only. Even if there had been a special appearance, said the court, it was waived by counsel's asking for affirmative relief. (Apparently, though the fact is not clear, the affirmative relief referred to as having been sought was the motion asking the director to vacate the order of revocation.)

The principal contention of the plaintiff seems to have been that the order of revocation was void because it was "relief of a different kind and in excess of the relief requested" in the original complaint, which remained unamended during the proceedings. But, said the court, it is elementary that the prayer of a complaint is not a part of the complaint. The prayer in this instance was the request in the complaint filed with the director that the plaintiff's license "to practice drugless healing" be revoked. Under the facts alleged in the complaint a cause of action was stated and it is not a controlling circumstance that the complaint was not amended so that the prayer would be to revoke her license to practice medicine and surgery. There is no basis for holding that the order revoking the license was void because the prayer of the complaint referred to drugless healing. The facts in this case, the court continued, furnish no basis for equitable intervention on our part. While it is true a party may obtain relief in equity against a judgment even after one year from the date of the entry of the judgment, nevertheless proper grounds for equitable intervention must be shown and that was not done here. Moreover, where a party has failed to make a proper defense at law through his own negligence, equity will not aid him. Even though a judgment may be inequitable, it will not be set aside nor will its enforcement be enjoined when it was the result of the complaining party's own fault or inexcusable neglect. In this case the applicable Washington statute gave the plaintiff the right to appeal from the order revoking her license if she acted within thirty days after the entry of the order. This was not done. Had it been done, any inequitable features surrounding the matter could have been corrected on appeal.

The judgment of the trial court adverse to the plaintiff was affirmed.—*Dale v Cohn, Director of Licenses, 127 P (2d) 411 (Wash., 1942)*

Healing Process of Wounds of Brain—Baggenstoss and his collaborators reviewed 70 selected cases in which ventricular puncture wounds had been made in the course of ventriculographic studies. There were many wounds from one day or less to two weeks of age but examples of wounds older than two weeks were more difficult to obtain. Wounds of seven days duration or less presented (1) a central zone of hemorrhage and necrosis and (2) a peripheral zone of edema and perivascular hemorrhages. Degenerative changes predominated in both zones but proliferation of endothelial cells of the capillaries and small blood vessels became evident on the fourth day and was fairly well developed by the seventh day. Between the seventh and the tenth day the zone of edema had been transformed into a zone of capillaries and proliferating endothelial cells and fibroblasts. A third zone, consisting of hypertrophied astrocytes peripheral to the zone of capillaries, also became apparent during this time. From the twelfth day on the process of organization continued and gradual absorption of the necrotic debris in the central portion of the wound and its partial replacement by a network of capillaries and fibroblasts occurred. After a month or two fibroblastic proliferation subsided but connective tissue fibrils were more numerous than before. Observations of wounds of six months duration or more indicated that the healing process had progressed slowly and that complete repair had not yet taken place. Observations of older wounds suggest that complete closure of the defect may or may not take place, depending on the extent of the original injury. Compared with wounds in other parts of the body there is a decided lack of vigor in the healing process of wounds of the brain, and repair takes place at a slow tempo. Repair is more vigorous in the cortex than in the white matter, but no difference could be detected as between children and adults. Astrocytes play a minor role in the reparative process. Microglial cells appear to play only a small role in the production of compound granular corpuscles.

Five Day Method of Treatment of Syphilis During Pregnancy—Twenty-seven pregnant women with syphilis were treated by the five day massive dose method. The majority were given concurrently arsenic and bismuth compounds. The treatment was well tolerated by both mother and fetus regardless of the stage of the pregnancy or the duration of the syphilis, whether primary, secondary or latent. Severe reactions or interference with the pregnancy were not observed. Of the 27 patients 1 was lost from observation, 25 have given birth to full term, normal infants. One syphilitic infant was born of a mother who apparently had acquired a second infection while the infant was still in utero. In addition to this group, 5 other patients who had been treated for early syphilis by the massive dose method later became pregnant and gave birth to normally developed seronegative infants although further antisyphilitic treatment was purposely withheld from the mothers. The results of the treatment on the mothers' syphilis were similar to results obtained in nonpregnant patients treated by the same method for similar types of syphilis.

Comparative Value of Digitalis and Ouabain—Digitalis and ouabain have similar but not identical action on the decompensated heart. Digitalis exerts a more pronounced effect on the functions of sinus excitation and the auriculoventricular

conduction, which it depresses, ouabain, on the contrary, acts primarily on the contractility and tonicity, which it stimulates. Digitalis chiefly affects the differentiated, neuromuscular tissue of the heart, ouabain the undifferentiated, contractile fibers of the myocardium. Digitalis administered by the oral route fixes itself slowly on the heart, ouabain administered intravenously acts rapidly. The maximum effect of digitalis is reached in two or three days, that of ouabain in one or two hours. Digitalis accumulates, ouabain does not. On discontinuance of the drug, digitalis extends its effect over a period of several days, up to eight or ten, the effect of ouabain disappears in twenty-four to thirty-six hours. The proper fields for digitalis are the congestive heart failure with tachycardia and especially with auricular fibrillation, fibrillation even in the absence of heart failure and long sustaining treatment of patients with slightly decompensated heart disease. The proper indications for exhibition of ouabain are the acute failure of the left ventricle and chronic failure of the left side of the heart in patients with vascular disease, such as coronary arteriosclerosis, hypertension and syphilitic aortitis. The author recommends one intravenous injection daily of 0.25 mg in a series of six doses and more according to the tolerance of the patient and the clinical improvement obtained. In thousand of patients treated over a period of twenty years he has not encountered a single death attributable to the drug.

Welding and Health of Worker—According to Brodie the intense ultraviolet rays at the welding arc may produce eye flashes. The arc is also responsible for the nitrous fume. Another source of danger involves the particulate fumes of iron, manganese, chromium, cadmium, nickel, zinc and magnesium. Other hazards are from fluorides, silicates, varnish, rubber and other substances. There is also oxygen deficiency if the welding is done in a confined space. In cutting galvanized pipes or welding sheets with the electric arc or acetylene torch, operators will develop metal fume fever because the galvanneal coating contains over 95 per cent zinc. A typical attack occurs after the man has left his work, i.e. several hours after exposure to the fumes. Sometimes during work he may notice a metallic taste and a dryness in the throat, or may feel a heaviness in the chest. After going to sleep he awakens with a feverish and breaks out in perspiration. His temperature is between 100 and 102 F. Such an attack lasts twenty-four to forty-eight hours. These workers often develop a resistance. Out of 100 workers exposed to galvanneal fumes, about 75 do not suffer at all, about 20 have chills and fever and only 5 have frequent attacks. Nitrous gas may be released for a local reaction in the lungs which may be fatal. It may lead to death. After exposure to the welding gas, the worker has an acid taste in his mouth and becomes coughy.

goes out into the fresh air his condition may improve considerably, but five or six hours later the cough returns in a more intensive form with shortness of breath cyanosis and a feeling of pressure in the chest. This may be followed by acute pulmonary edema with profuse expectoration of frothy, yellowish or pinkish fluid. Heart failure and death may follow in forty-eight hours. If the amount of nitrous gases inhaled is smaller, the patient may develop not pulmonary edema but pneumonia or acute bronchitis. Welding is not a hazardous occupation provided the concentration of fumes is kept at a low level. Although after many years of welding the lungs may show certain fibrotic or nodular changes which in an x-ray film may remind one of early silicosis there is neither the shortness of breath nor the tendency to tuberculosis which is seen in silicosis. It is important that the physician realize the essential harmlessness of these so-called spots on the lungs so that he may be able to explain away the fears of his patient and reassure him.

Recurring Vesicular Eruptions of Hands—Davidson and Birt discuss the various types of recurring vesicular eruptions of the hands and present a classification based on the causative agent which may act directly or from a distance. A survey was made of the records of the last 200 patients in whom the chief complaint was an eruption localized mainly to the hands and featured by the presence of vesicles. Dermatitis venenata accounted for three fourths of all the cases. If this group characterized by acute inflammatory reaction is excluded, the relative importance of the other conditions becomes evident. More than half of the remaining cases were diagnosed as cheirpompholyx and only about one third were dermatophytids. Because of the relatively high incidence of cheirpompholyx found here an additional 134 cases were included from the records making a total of 175 patients with cheirpompholyx. Cheirpompholyx occurred about evenly in the two sexes, was commonest in the third and fourth decades of life most often affected those engaged in white collar occupations and appeared chiefly in hot weather. Many of these patients had hyperhidrosis of the hands and feet, and outbreaks were often associated with nervous strain. It would seem that there is ample justification for such a diagnosis as cheirpompholyx, that it can occur in the absence of mycotic infection that there are probably constitutional reasons for the attacks and that the attacks are dependent to some extent on the weather. It is suggested that the incidence of dermatophytids recorded may depend to some extent on the interpretation given to the so-called mosaic fungus. This fungus is commonly found on microscopic examination of scrapings taken from the feet and mounted in potash. It is in reality not a fungus but is formed by flat rhombic crystals of cholesterol. It is possible that the interpretation given to the presence of the mosaic may account for some of the conflicting opinions regarding the part played by fungi in the production of vesicular eruptions of the hands.

Electric Shock Therapy in Psychoses—Epstein records observations on electric shock treatments administered to 100 patients of whom 37 had manic depressive insanity, 37 dementia praecox, 16 involutional psychoses and 10 undifferentiated psychoses. The ages of the patients varied between 16 and 73 years. He conceives of electric shock as a mass irritation or stimulation to the cerebrum, the intensity of the reaction being somewhat proportionate to the amount and force of the current. Irritation of the autonomic nervous system is expressed by changes in the size and reaction of the pupils, rate and rhythm of the heart, blood pressure respiration, sweating and the like. Motor irritation is expressed through muscular movements, changes in reflexes, and signs of pyramidal tract irritation. Mental reactions are in the nature of confusion, disorientation and amnesic or aphasic states. When the mass irritation is at its maximum, a convulsion is associated with these phenomena. The author empirically designated the degree of the reaction in terms of from 1+ to 4+++. The 1+ is the mildest type of petit mal response and 4+++ is a severe convulsion associated with prolonged apnea and frequent cardiac standstill. Convulsive reactions are most desirable for treatment purposes but 3+ petit mal reactions can be satisfactorily utilized in certain instances. Patients with manic depressive insanity and those with involutional melancholia responded best to electric shock treatment. Dementia praecox and mixed psychoses in which paranoid and delusional trends predominated responded poorly. When the duration of the illness was less than six months the general outlook for improvement or recovery was better, irrespective of the type of psychosis. Electrocerebral shock is more easily administered and less hazardous than insulin or metrazol.

Landry's Paralysis—Hassin describes the case of a boy aged 12 who died after an illness of seventy-two hours with respiratory difficulties. Necropsy revealed disseminated inflammation of both the gray and the white substance of the brain, pons, cerebellum, medulla and spinal cord, with disappearance of many nerve cells especially in the spinal cord and the medulla, cloudy swelling of the liver, kidneys and the heart, which exhibited indistinct cross striations with increased amount of connective tissue about the arterioles and small focal and diffuse accumulations of inflammatory cells (leukocytes, histiocytes) and scattered hemorrhages. Microscopic studies were made on the muscles. The parenchymatous changes consisted of swelling and disruption of the muscle fibers into fibrils and wavy degeneration. There were inflammatory changes in the form of focal and diffuse infiltrations with fibroblasts and lymphocytes. The changes were confined to the diaphragm and the intercostal and pectoral muscles but were especially in evidence in the musculature of the heart. The author stresses that in this case of poliomyelitis microscopic changes were present not only in the central nervous system but also in some muscles. He thinks that involvement of the muscles may be the essential pathologic feature in those cases in which no changes were found in the nervous system (central, peripheral or sympathetic). Like the Brown-Sequard paralysis, Landry's paralysis is not a morbid entity but a symptom complex. In all cases with a clinical picture of Landry's paralysis the muscles, especially those of respiration, should be examined carefully. It is even more important to ascertain the condition of the heart, which may be responsible for the rapid and often fatal course.

Immunization Against Rheumatic Fever—After nine years of experience with immunization, first with crude and later with attenuated hemolytic streptococcus toxin, against recurrences of rheumatic fever attacks, Wasson and Brown feel that they can state that the children suffer no harm and that in most cases they are much benefited by the prophylactic treatment.

Massive Doses of Vitamin D in Rickets Prophylaxis—Rambar and his co-workers found that the use of a single massive oral dose of an electrically activated vaporized ergosterol, containing 600,000 U S P units of vitamin D, was effective in preventing rickets in a group of infants studied during the fall and winter months. The use of repeated smaller doses of 100,000 U S P units of the same antirachitic agent given monthly during this period (October to April) was effective also in preventing rickets in each of the infants studied. No toxic clinical or laboratory findings occurred in any of the infants receiving this type of prophylaxis.

Plasma Ascorbic Acid Levels in Nebraska Children—Gedgoud and his collaborators show that attempts to evaluate levels of ascorbic acid in the plasma in children have led to a variance of opinions. Doubt has been expressed as to whether or not a level of 0.7 mg per hundred cubic centimeters or more is actually the standard toward which to strive. The present investigation seeks to throw further light on these problems, utilizing children admitted to the University Hospital in Omaha from every part of the state of Nebraska and representing the lowest income group. On a daily intake of from 60 to 80 mg of ascorbic acid a level of 0.7 mg per hundred cubic centimeters or more was attained in 81 per cent of children entering the hospital without infection, regardless of the entrance value. The ease of attaining a value of 0.7 mg per hundred cubic centimeters or more indicates that 36.4 per cent of "healthy" children were probably on a diet containing less than from 60 to 80 mg daily and that levels of from 0.4 to 0.69 mg per hundred cubic centimeters may still be considered "borderline." In 2 healthy infants entering with plasma levels in the borderline (0.4 to 0.69 mg per hundred cubic centimeters) zone, 60 to 80 mg of ascorbic acid daily did not raise the level beyond 0.7 mg per hundred cubic centimeters over observation periods of from eighteen to nineteen days. This is an incidence of 2 in 96 cases. Of 12 children with infections, from 100 to 150 mg daily was adequate to raise the plasma level to 0.7 mg per hundred cubic centimeters or more in 11 over periods of from three to twenty-one days. Only 1 "healthy" child persisted in maintaining a low level of plasma ascorbic acid on an intake of from 60 to 80 mg daily during eleven days of observation.

Treatment of Tonsillitis with Bismuth Salt of Heptadienecarboxylic Acid in Suppositories—Thirty-two patients with tonsillitis, pharyngitis and gingivostomatitis were treated by Silber with suppositories containing the bismuth salt of heptadienecarboxylic acid. Subjective symptoms disappeared within twenty-four to forty-eight hours after treatment was begun. The temperature dropped within twenty-four hours and was normal in from thirty-six to forty-eight hours in most cases. Signs of local improvement appeared within twenty-four hours. In patients in whom attacks of a similar nature had occurred, whatever form of treatment was used, the duration of the illness was much longer than in those treated with bismuth. No more than two suppositories at twenty-four hour intervals were required in all but 1 patient. There were no local ill effects from the use of the suppositories. There were no toxic reactions to bismuth. The method has advantages over other methods, including the sulfonamides and arsphenamines, because of the ease of administration, the freedom from danger of toxic reactions, the sparing of the sulfonamides for conditions in which their specificity and definite indications more strongly require their use, and the avoidance of production of sulfonamide resistance or sensitivity by their use in conditions in which another medicament of proved equal or greater value is available.

Prothrombin Deficiency in Biliary Obstruction and Diseases of Liver—Maintenance of normal plasma prothrombin, according to Herbert, depends on an adequate supply and absorption of vitamin K. The deficiency can be rapidly corrected by injection of vitamin K or its analogues. Estimations of plasma prothrombin often give warning of the risk of post-operative hemorrhage in cases in which there is no spontaneous hemorrhage and no abnormality in coagulation time or bleeding time. The estimation of prothrombin is therefore a useful clinical test, indicating when prophylactic treatment is necessary. There is usually a fall in plasma prothrombin following operations on the biliary tract so that a normal value before operation does not necessarily exclude the risk. She describes a two stage method of estimating plasma prothrombin. The method was used in 51 cases with obstructive jaundice and with serum bilirubin levels over 2.4 mg per hundred cubic centimeters. Of these 68 per cent showed hypoprothrombinemia and in 30 per cent the titers fell below 50 per cent of the normal average. These results are closely similar to those obtained by Brinkhous, Smith and Warner and by Stewart and Rourke with the two stage method although there is a slightly higher

proportion of normal results in the present series. In 40 cases of liver disease studied in the present series 68 per cent showed hypoprothrombinemia and in 25 per cent the titers fell below 50 per cent. In some cases hypoprothrombinemia was found when the jaundice was extremely slight. Cases are quoted of the restoration of the plasma prothrombin level to normal by treatment with menadione in cases of biliary obstruction, and of failure of this treatment when there was damage to the hepatic parenchyma. When normal plasma prothrombin exists before operation hypoprothrombinemia and hemorrhage may develop a few days after the operation.

Effect of Vitamin A on Acne—Straumfjord points out that explanations offered for the causation of acne are obscure and conflicting. The basic primary lesion of acne is a hyperkeratosis of the pilosebaceous follicle identical with the hyperkeratosis described in vitamin A deficiency. During the last five years approximately 300 cases of acne were seen at his clinic. Vitamin A was prescribed in high dosage. The data obtained from 100 patients were sufficient for analysis. These 100 patients were treated with a supplement of approximately 100,000 international units of vitamin A daily for six months and longer. Seventy-nine became free or nearly free from the eruption and only three were unimproved. The response of follicular hyperkeratosis and of acne to the administration of vitamin A suggests that their cause is the same, that both are cutaneous lesions of vitamin A deficiency.

Extent of Immunization in Large Cities—The study is based on a canvass of 213,931 households in twenty-eight cities of 100,000 or more population selected as representative of cities of that size in different geographic sections. Immunizations against scarlet fever and typhoid are negligible in frequency as compared with those against diphtheria and smallpox. In the preschool ages diphtheria immunizations are more

frequent than smallpox vaccinations, but after five years the reverse is true. At 8 years of age 61 per cent of the children had been immunized against diphtheria and 85 per cent had been vaccinated against smallpox at some time since birth. There is considerable geographic variation in the extent of immunization against these diseases. These twenty-eight large cities were divided into five geographic groups, Northeast, North Central, Intermediate, South and West. In diphtheria immunizations the West is lowest from birth through 7 years, but beyond that age the South is lowest, the Intermediate is highest from birth through 5 years, but after 6 years the Northeast and North Central are above the Intermediate. The South and Intermediate cities are highest in history of diphtheria cases. In smallpox vaccinations the Northeast, Intermediate and South all get above 90 per cent by about 8 years of age, but the North Central and particularly the West are low, the latter reaching only about 60 per cent. In history of smallpox cases the West is above any other section. In scarlet fever immunizations the West and North Central are far above the other sections, but no region gets above about 5 per cent. In scarlet fever cases the North Central and Intermediate are at the top. In typhoid immunizations the South is far above any other section, with the West second. The South shows the highest history of typhoid cases. The numbers of scarlet fever and typhoid immunizations are too few in any section to have any definite effect on the course of these diseases, the immunized, therefore, represent protection for certain individuals only, and the highest immunization rates show up where case rates are high enough to stimulate the use of the vaccine. When children were classified according to family income it was found that in the preschool ages the percentages of children who had been immunized against diphtheria and smallpox increase definitely with income. The same was true for diphtheria immunizations during the school ages, but there was little difference in smallpox vaccinations as between high and low incomes. Scarlet fever and typhoid immunizations increase with income in each of the three age groups under 15 years, indicating that these immunizations are largely the result of individual initiative rather than public programs.

Perforating Gallbladder—Hicken and Coray present a study of 24 cases of perforated gallbladders. The complication occurred in 25.6 per cent of all cases of acute cholecystitis which the authors have seen. They maintain that acute cholecystitis constitutes the same type of surgical emergency as does acute appendicitis, except that it is even more urgent. Many appendicular crises would subside if treated conservatively, yet immediate surgery pays good dividends. In acute cholecystitis corrective operations should be employed as soon as the patient has been properly prepared. This requires but twelve to twenty-four hours to accomplish. Clinical signs and symptoms, laboratory data and roentgenologic studies have all been unreliable in determining which "acute gallbladders" will subside and which will become progressively worse, hence surgical intervention is imperative. Spinal anesthesia is the agent of choice. It is nontoxic to the liver, provides complete muscular relaxation and effectively collapses the distended intestines, thus expediting surgical explorations. The operation must be selected to fit each individual case. In every instance the common bile duct must be explored either roentgenographically by means of cholangiograms or surgically before disturbing the gallbladder. Whenever possible the gallbladder should be removed. The postoperative care is essential and aims at maintaining the essential physiologic processes at a normal level. Postoperative cholangiograms are used to determine the proper time for removing the choledochal drains. The mortality rate for this series was but 9 per cent. Acute cholecystitis and perforations of the gallbladder are both preventable complications of chronic cholecystitis. Operations during the chronic phase would eliminate these exacerbative reactions.

Congenital Cerebral Aneurysms Lateralized by Electroencephalography—Woodhall and Lowenbach describe a method of lateralization of the bleeding point in cases of spontaneous subarachnoid hemorrhage by the use of electroencephalography. The method is based on experiences in 3 cases showing a neurologic defect and in 3 selected cases in which neurologic changes. The aneurysms in the first group were demonstrated at operation. In all of the cases the aneurysm was visualized by arteriography using 20 per cent diatrizoate. The electroencephalographic signs which the authors regard as characteristic consist of a more or less constant asymmetry of amplitude, frequency and wave form between the tracings obtained from the two hemispheres.

findings present over the hemisphere containing the bleeding point. This abnormal activity may be due to relative cerebral anoxemia resulting from rupture of a congenital cerebral aneurysm the common cause for such hemorrhages.

Plastic Gels as Vehicles for Sulfonamides—Hare and Clark attempted to find a suitable method for the first aid treatment of persons wounded in battle who may be compelled to lie unattended for days before proper surgical treatment becomes available. Sulfanilamide alone or incorporated in a vehicle leaves much to be desired, for it is absorbed within the first twenty-four hours. Sulfathiazole without a buffer is much more slowly absorbed than sulfanilamide because it is so much less soluble. It also acts on a greater variety of clostridia than sulfanilamide and may even have some action on staphylococci. When the unbuffered drug is employed, an effective potential is maintained for only sixty hours and the formation of crystals is a great drawback. When the drug was incorporated in a plastic material, such as methyl cellulose, the effective concentration was maintained for much longer periods and crystal formation was not observed. Another advantage is its ability to absorb three to eight times its own weight of serum or plasma. This will tend to facilitate soaking up of oozing blood and serum, in this process the vehicle swells, and, if a tight bandage is applied, the pressure exerted by the swelling may prevent further capillary bleeding and may even arrest venous hemorrhage. Methyl cellulose is freely soluble in water and can be picked or washed out at debridement. Because methyl cellulose is not absorbed by plasma or other tissue fluids, primary or even secondary suture cannot be carried out until it has all been removed. Autoclaving decomposes sulfathiazole, but hot air sterilization has no deleterious effect. Satisfactory sterilization may be obtained by heating in hot air at a temperature of 140 C for three hours.

March Fractures of Lower Extremity—Childress points out that march fracture has long been considered synonymous with march foot. Recently, more attention has been given to similar fractures occurring in the long bones of the lower extremity. Terms used to designate this lesion include incomplete, exhaustion, insufficiency, false spontaneous, creeping

chronic, fatigue stress, insidious and soldiers' fracture. March fracture of the foot is the most common of all march fractures. Next in frequency are march fractures of the tibia. March fracture of the fibula usually occurs near the proximal or the distal end of the bone. March fractures of the femur occur in the lower portion of the shaft and at the neck. Occasionally the pelvic bones may develop march fractures. Regardless of the bone involved in march fracture, the onset and progression are much the same. The lesion is produced by repeated minimal trauma, which by summation causes an overloading of the functional capacity of an otherwise normal bone. This occurs particularly in soldiers carrying packs and in workers performing heavy labor. The onset may be acute but is usually insidious. The pain is dull and vague at first and is initiated by prolonged periods of weight bearing. Rest gives complete relief. With continued activity the pain increases in severity. A localized swelling of soft tissues develops in association with tenderness on deep pressure. The overlying skin may be slightly reddened with increased heat. Immediately after onset roentgenograms of the involved bone usually do not reveal anything abnormal. A faint incomplete fracture line may be demonstrated. In two to three weeks callus is noted. Diagnosis in many cases is not made until a large amount of callus has been formed. In the foot this osseous mass may exert pressure on adjacent soft structures and thus produce considerable pain. Complete rest of the part is indicated in order to decrease the size of the callus also to prevent a refracture. Adequate support must be maintained until full healing has been obtained. Osteogenic sarcoma, Ewing's tumor, nonsuppurative osteomyelitis and syphilitic periostitis should be differentiated from march fracture. Before a biopsy is done the bone should be observed clinically and roentgenographically during and after a few weeks of complete rest of the affected part. To decrease the incidence of this fracture a gradual physical build-up should be given to both army recruits and formerly unemployed civilian workers. The author reports a case of march fracture of the cuneiform bone. His review of the literature failed to disclose another solitary march fracture of the cuneiform bone. He suggests that many may have occurred but have been treated under other diagnoses.

Two Stage Amputation—Jack and Charnley show that the procedures at present in vogue for amputation accept infection of the stump as inevitable. The guillotine seeks to sidetrack it, the loose closure method to minimize its effects. The two stage amputation employs two principles. First, to combat implanted or invading organisms, sulfanilamide powder is introduced into the wound in large quantity to maintain a high local concentration. Second, to counter the predisposing conditions a large dry gauze pack is sutured under the flaps with its ends left projecting from the corners of the incision. The pack must be large so that the flaps are sutured over it under moderate tension approximating that obtaining in normal tissues, it must be of dry gauze so that it is absorbent. There is an outpouring of serum from the raw surfaces, which soaks into the pack. By the capillary action of the gauze it is conducted out. At the same time a proportion of the sulfanilamide is dissolved by the serum and the pack becomes a reservoir of sulfanilamide in high concentration. The tension of the flaps over the pack maintains the circulation as normal as possible, and at the same time an even pressure is produced over the whole surface of the wound, thus preventing edema and promoting effective hemostasis. The first stage starts as a standard flap amputation at the site of election. The second stage should be performed four or five days later. The two stage method has been used in 26 cases. Primary healing without complication was obtained in 18. In 3 others the skin margins slid apart for about half an inch but healed without sepsis when they were drawn together with strapping. Three cases developed sepsis at the skin edges, which did not interfere with the healing. Only 2 cases developed severe infection with suppuration. The two stage amputation has yielded impressive results. Should it fail in its object of preventing infection, no harm has been done. The two stages of the procedure fit logically into the average time lag between forward area surgery and arrival at a base hospital.

Early Treatment of War Wounds of Upper Part of Face—Oldfield emphasizes the following six elementary principles in the early treatment of wounds of the upper part of the face. 1 Cleanse the wound most thoroughly with soap and

water, peroxide and saline solution. 2 Never excise a facial wound. 3 Save the framework of the face even if it is loose, sacrifice a bony fragment only if it is completely detached from all the surrounding tissues. 4 If there has been any skin loss, pack the wound with sulfanilamide powder and leave it open. 5 If there has been no skin loss and the wound is recent, insert fine silk stitches and remove them within three days. 6 In the face, never insert a few big stitches under tension, they usually lead to serious septic complications and will always be followed by an irreparable scar, which will remain a disfigurement for life.

Generalized Vaccinal Reactions in Allergic Subjects—Davidson and Davis report observations during the recent small outbreak of smallpox in the Edinburgh area, when a large proportion of the population was vaccinated or revaccinated. Four patients manifested generalized complications after vaccination in whom there was presumptive evidence of an underlying allergic diathesis. The ages of the patients varied between 4 and 40 years. The abnormal reactions appeared from eight to ten days after the vaccination. Purpuric manifestations appeared in 3 of the patients, 2 of whom developed well defined edema at the same time. The remaining patient showed generalized vaccinia. These abnormal reactions may be related to an allergic tendency, since in case 1 there was a personal and in case 2 a familial history of allergy, and in the other 2 cases there were clinical grounds for postulating the presence of abnormal sensitivity.

*Suprapubic Catheterization for Paralysis of Bladder C A F and E M Widdowson—p 128

Injuries Produced by Blast in Water—Goharier and Simmons report a clinical and pathological study of 17 water blast injuries. All of the men were suffering from lesions to the abdomen. The lesions found were confined to the intestine, stomach and lower end of the bladder and consisted of intramural hematomas and perforations.

tortions occurred only in the small intestine and were present in 9 cases. The only constant sign of injury outside the alimentary tract itself was a retroperitoneal hemorrhage behind the right colic flexure. The solid abdominal organs escaped injury. Seven cases showed signs of injury to the lungs, and the pulmonary hemorrhages were identical with those described in bomb blast casualties. In the differentiation of perforating from nonperforating abdominal lesions the features of diagnostic value were persistent severe abdominal tenderness and rigidity together with elevation of the pulse rate of patients with perforations. In cases in which perforating injuries were diagnosed or could not be excluded laparotomy was performed. Because of the associated lung injuries, infusions of plasma and blood were as far as possible avoided, but it was not always practicable to dispense with them entirely. Of the 9 patients with intestinal perforation 2 were too ill to stand operation and died and 7 were operated on with four deaths. Of the 8 cases with nonperforating lesions 6 were treated conservatively with one death (from shock immediately after admission) and in 2 in which the diagnosis was doubtful laparotomy was done with recovery. The causes of death were shock, the lung injury and in 1 case peritonitis.

Suprapubic Catheterization for Paralysis of Bladder in Spinal Injury—Riches deplores that there is still no agreement on the treatment of a bladder paralyzed as a result of spinal injury. He shows that a safe and rapid method of suprapubic catheterization has now been devised. It has been used successfully as a means of bladder drainage in more than 20 surgical cases and in a few cases of spinal injury. The simple instrumentarium and the technique are described. After paralysis from spinal injury the bladder should be allowed to distend. When it is distended, suprapubic catheterization should be performed. Tidal drainage should be added after two days. The use of a urethral catheter in the treatment of the paralyzed bladder should be forbidden.

Fractures and Dislocations of Cervical Part of Spine—West observed a series of cases of injuries of the cervical portion of the spine, chiefly following accidents in the surf. He gives a detailed description of 2 cases to illustrate the management of such lesions. He recommends a light type of plaster cast, which he describes and illustrates. A short period of immobilization and the avoidance of heavy types of plaster casts will lessen the incidence of neuroses in these cases.

Table Knife Lying in Peritoneal Cavity for Five Years. I. Gordon. —p. 187.

Table Knife Lying in Peritoneal Cavity for Five Years—Gordon reports the history of a truck driver who complained that for the last three months he had experienced discomfort in the region of the right ischio-rectal fossa. A tender lump was found near the skin in the right ischio-rectal fossa. X-ray examination showed a table knife in the abdomen with the point near the skin at the tender spot. He had been admitted to the hospital five years previously suffering from a stab wound of the upper abdomen. At that time the symptoms suggested an injury to the lung. The chest was X-rayed and

nothing abnormal was noted. The entrance scar was situated just below the left costal margin 2 inches from the midline. X-ray examination now showed the handle of the knife in the upper end at McBurney's point and the point of the blade in the right ischio-rectal fossa. No evidence of damage to the stomach or the intestine was found when the abdomen was opened. The knife was lying free in the peritoneal cavity. A sausage shaped roll of omentum completely surrounded the knife, forming a sheath extending down into the pelvis. This sheath was opened and the knife was extracted without difficulty. The patient was discharged on the seventeenth day. The blade of the knife, which was 8 inches long, was as bright as if it had just been polished. There was no evidence of any rusting, nor had the color of the bone handle changed.

Does Fetus in Utero Become Involved in Poliomyelitis During Pregnancy? J.otti Hurny. —p. 1417.

Vitamin Supply for Pregnant and Nursing Women—Neuwider studied the vitamin supply of pregnant and nursing women. Although many of these women receive some added rations, these will be divided among a family and the pregnant or nursing woman will receive only a part of the ration. Neuwider determined the vitamin C content of the blood according to the method of van Eckelen and Emmerie in three groups of 40 women each. One group comprised nonpregnant women, one pregnant women and one nursing women. The results were compared with those obtained in similar groups in 1937 and 1938. During the summer of 1942 the values were much lower than they had been during the summer of 1938 and during the winter of 1937. The values were most unfavorable in the blood of nursing mothers. Investigations on the vitamin C content of breast milk, however, revealed practically the same values as during the previous years. Apparently the danger of hypovitaminosis in the nursing mother is greater than in other women because of considerable diminution into the milk. Physicians should inform themselves regarding the diets of pregnant and nursing women and should prescribe vitamin preparations if the diets seem inadequate. Attention should be given not only to vitamin C but also to vitamins of the B group and to vitamin A.

Sulfathiazole in Otitis Media—Hild treated 180 cases of febrile acute otitis media with sulfathiazole, 168 responded favorably while 12 were uninfluenced. Antrotomy was necessary in 7 cases. It was found that in the cases treated with sulfathiazole the time necessary for cure was shortened by one third in comparison with the cases in which no sulfathiazole was employed, surgical treatment was required only one fourth as frequently. Sulfathiazole was administered only in the form of tablets, the oral administration answered all requirements. The simultaneous administration of 25 per cent solution of nikethamide counteracted the occasional occurrence of nausea and vomiting. The total dose of sulfathiazole was 16 Gm for adults, 9 Gm for children between 2 and 12 years and 6 Gm for children less than 2 years of age. These doses were given in the course of six days, larger doses being given on the first two days. Serious secondary effects were not observed. The sulfathiazole was particularly effective during the first five days after the onset, but even during the later stage noticeable effects were obtained. Inspection of the tympanum and testing of the hearing by whispering should be done during the entire course of the chemotherapy because these tests reveal an otherwise unnoticed advancement of the disease process and make possible the consultation of a specialist in doubtful cases.

Poliomyelitis During Pregnancy—Hurny reports the histories of 2 women who developed acute anterior poliomyelitis at the end of their pregnancy. In both patients cesarean operations were done. All three children (1 set of twins) were and remained healthy but both mothers died as the result of Landry's type of poliomyelitic paralysis shortly after the

cesarean operation. This indicates that the placental barrier is impermeable for the virus of poliomyelitis. The literature contains only few records of similar cases. Three of these are cited by the author. In these the children also remained healthy. The transmission of antigens was examined in only 1 of the cases reported in the literature. In this instance, in which the child was born four and one-half months after onset of the poliomyelitis, the antigen titer was unusually high.

Cerebral Symptoms of Lymphogranulomatosis (Hodgkin Sternberg's Disease) J. R. Garcia Martin—p. 386
Vascular Collapse in Obstetrics R. Garcia Pastor—p. 394

Cerebral Symptoms of Lymphogranulomatosis—Garcia Martin directs attention to the cerebral form of lymphogranulomatosis, of which a case is reported. A man aged 32 presented typical lymphogranulomatosis of two years' duration. The diagnosis was verified by a lymph node biopsy. In the course of the disease there developed anarthria, which did not improve on administration of arsenicals and roentgen therapy. Three months later there were irritability, mental confusion and acute epileptiform attacks. Lymphogranulomatosis is caused by a virus with a selective localization in the lymph nodes or in the entire lymphatic system and rarely in the nervous tissue. In the reported case the virus was localized in the cortical centers of speech and in the psychomotor zones.

Mycotic Ulcer of Cornea F. L. Niño—p. 797
Heart Disease and Liver Function M. Bernstein, E. B. Le Win and S. Simkins—p. 816

Coagulation of Blood in Intermittent Claudication and Gangrene of Lower Extremities—Di Cio and Bay studied 86 patients with peripheral vascular diseases. Lee and White's technic, in which coagulation between five and eight minutes is considered normal, was used. Tanturi-Banfi-Quick's modified technic for determining the time of formation of prothrombin and the concentration of prothrombin in the blood, in which a time of formation of prothrombin between eighteen and twenty seconds and a concentration varying between 80 and 110 mg per hundred cubic centimeters of blood are considered normal, were also used. The time of blood coagulation was diminished in 10 of 19 cases of intermittent claudication without arterial blood hypertension, in 22 of 32 cases of intermittent claudication with arterial blood hypertension, in 4 of 7 cases of intermittent claudication with intestinal parasitism, in 10 of 18 cases of gangrene of the lower limbs without arterial hypertension and in 6 of 10 cases of gangrene of the lower limbs with arterial blood hypertension. Blood coagulation time was normal in the remaining cases in each group. The time of formation of prothrombin and the concentration of the substance in the blood were normal in all cases. The authors believe that the diminished blood coagulation time is due to a diminished concentration of heparin and other anticoagulating substances in the blood.

Otitis Media and Its Complications in Diabetic Patients F. de Paula Pinto Hartung—p. 5
Total Destruction of Tongue Due to Carcinoma E. Moreira—p. 97

Otitis Media in Diabetic Patients—De Paula Pinto Hartung directs attention to the grave prognosis of acute otitis media in diabetic patients. The success of therapy depends on maintaining the patient on a correct antidiabetic diet and on proper doses of insulin and sulfanilamide in preparation for operation when the latter is indicated. Coma following on the appearance of labyrinthine symptoms and in the course of pneumococcal meningitis complicating the otitis media does not constitute a contraindication to an operation, which should be performed without delay. A man aged 35, with diabetes, had an attack of acute otitis media. He improved on sulfanilamide therapy, insulin and proper diet. A mastoidectomy performed

for symptoms of mastoid involvement was followed by improvement which lasted two months, after which the patient developed acute meningitis and coma. The cerebrospinal fluid was under increased pressure, was purulent and contained pneumococci. The patient recovered after an operation, sulfanilamide and insulin therapy.

Treatment of Hormonal Disturbances with Estrogenic Stilbestrol Preparations O. Bauer—p. 369
Morphology of Symptom of Infantile Little Finger Maria Lutz—p. 371
Development of Malarial Sporozoites in Warm Blooded Animals W. Schulemann—p. 374
Occurrence of Wallgren's Epidemic Serous Meningitis in Hungary R. von Engel—p. 379

Symptom of Infantile Little Finger—Lutz points out that the symptom of infantile little finger was first described by Du Bois in 1926 under the term "auriculaire infantile" and was identified by him as a sign of congenital syphilis. After citing and evaluating subsequent reports on this sign, the author describes her own studies on the basis of roentgenograms. In a normal hand there exists a definite ratio between the different parts of a finger as well as between each part of a finger and the corresponding part of the other fingers. The shortening of a bone becomes manifest in a shifting of this ratio. The author investigated these ratios roentgenologically in 7 normal hands and in 20 hands with the symptom of infantilism of the little finger. She emphasizes that the shortening of the little finger is due either to a noticeable isolated shortening of the fifth metacarpal or of the middle phalanx of this finger or it results from a summation of minimal shortenings of several bones. Roentgenoscopy shows that in the normal hand the second interphalangeal cleft of the little finger is considerably distal to the first interphalangeal cleft of the fourth finger. In the hand with the little finger sign, however, the two clefts are in the same line or the little finger cleft is proximal to that on the fourth finger. Roentgenologic examination is not always necessary, since Hissard's description of the relative shifting of the skin folds usually indicates the bone shortening. Shortening of the fourth finger is occasionally added to the infantilism of the little finger. If such bone metaphasias are unilateral they can be designated as finger asymmetry, which is likewise a sign of congenital syphilis.

Development of Malarial Sporozoites in Warm Blooded Animals—Schulemann points out that experimental studies by Missiroli and by Kikuth and Mudrow proved that the sporozoites of the malarial plasmodia do not attack the erythrocytes of warm blooded animals directly but pass through an intermediate development. Considerable discussion arose regarding the intermediate stages. The author made studies with an improved technic. Salivary glands of *Culex pipiens* which contained sporozoites of *Plasmodium cathemerium* were crushed with canary serum. This suspension was stained with trypan violet and then injected into the subcutaneous fat of canaries. The injected area was excised twenty-four, forty-eight, sixty-three and ninety-nine hours after injection. At the end of twenty-four hours the majority of sporozoites appear as slender forms with one but mostly two and rarely three chromatin granules. In some of the sporozoites the protoplasm shows slight swelling. In the sporozoites that have two chromatin granules it can be seen that the granules become separated and shift to the ends. In injected areas removed later (after forty-eight, sixty-three or ninety-nine hours) the swelling of the protoplasm increases continuously. The chromatin granules likewise grow, the lacings in and the later complete division of the protoplasm between the chromatin granules progresses and division follows. The resulting mononuclear round forms develop into polynuclear forms. The sectioned specimens show that the described sporozoites are extracellular. Later development is extracellular as well as intracellular. The author thinks that it is too early to decide definitely where and in what manner sporozoite development takes place. His observations so far seem to prove Missiroli's claim that there is a division of sporozoites. The later development is more varied than has hitherto been believed.

Book Notices

Allergy By Irish Urbach MD Chief of Allergy Service Jewish Hospital Philadelphia with the collaboration of Phillip M Cottlieb MD Associate on Allergy Service Jewish Hospital Fairbaird Price \$12 1p 1077 with 396 illustrations New York Grune & Stratton 1947

This is the most ambitious work on allergy in recent years. The massiveness of this volume of more than a thousand pages, with 2,262 references appearing as footnotes indicates the thoroughness of the work. The illustrations are excellent in reproduction and choice. It is a reference work which the specialist in allergy will appreciate for its thoroughness in both allergy and applied immunology. Whether physicians other than specialists will equally appreciate it will depend on the degree of their interest in allergy and immunology. The very completeness with which the literature is covered and the thoroughness of many of the discussions may overwhelm the reader who is not definitely interested in these subjects.

This book is divided into three parts. In part I, covering the first 283 pages, the author discusses the fundamentals of allergy from the point of view of the immunologist. An excellent and clear presentation with a thorough review of the literature is given of this subject. However, the weakness of this entire work first appears in this section. The author rejects Pirquet's concept of allergy as too broad. For it he substitutes his own classification—a very complex one requiring many obscure terms coined by the author or by other Europeans but not generally used or accepted in the American literature. The following are a few examples: pathergy, allergization, deallergization, parallelism, metallurgy and many other newly coined or generally unaccepted terms. Our knowledge of immunology and certainly of allergy is today too limited to warrant burdening it with a multiplicity of new terms for the sake of the 'working hypothesis' of any one man. If the critical reader will disregard this objection he will find in this section an excellent discussion of immunity as related to allergy and of the identity of anaphylaxis and atopy.

The latter part of this first section deals with the methods of diagnosis and with the general methods and principles of treatment. Here much controversial material will be found. It starts with such a simple subject as the technique of performing intradermal tests (p 237). Among the precautions advised by the author are that no two biologically related substances should be used simultaneously for testing. This would be acceptable as justifiably cautious if the author had not selected as his examples goose and chicken feathers. Feathers are among our weakest allergens. Systemic reactions to them are either rare or unknown. A less understandable error in this section is the advice to withdraw the plunger (intracutaneous tests!) and observe for blood as a precaution against the needle being in a blood vessel before injecting the materials. A dermatologist of Urbach's experience could not have written such advice except through inadvertent error.

More serious than these objections is the emphasis on "deallergization" (primarily by oral therapy) as a method of preference over hyposensitization. Here Urbach emphasizes his use of protein digests, propeptans, to "deallergize" most allergic conditions. Despite the fact that Urbach introduced this form of 'propeptan' therapy in 1930, workers in this country still have not accepted this method of treatment. Most reliable workers who have experimented with it reject it as a method of treatment although they admit that their experience with this form of therapy is limited. Urbach's explanation of these carefully qualified but unfavorable reports is that these workers used their own protein digests rather than those prepared by Urbach (p 268). This defensiveness is unjust to such careful workers as Bray, Rowe, Vaughn and C J White.

Part II, consisting of about 260 pages is devoted to a thorough discussion of the etiologic agents of allergic diseases. The classic division used is that of inhalants, ingestants, injectants, contactants, physical agents and infectants. These subjects are likewise thoroughly presented. The part which the reviewer considers especially excellent is the discussion of allergy and immunity in acute and chronic diseases. The principles of allergy and immunity as revealed in the studies of

tuberculosis and syphilis are particularly well correlated with what is usually classified as the "allergic diseases."

Finally, part III presents the symptomatology and therapy of allergic diseases. This part covers about 150 pages, of which the last hundred are relatively unimportant since they cover the more unusual and questionable allergic entities, as allergy of the eye, the ear, the nervous system, the cardiovascular system and the joints. In this section also the one serious objection the reviewer finds is the disproportionate importance placed by Urbach on oral therapy in such a condition as seasonal hay fever. From the material presented here the reader inexperienced in allergy cannot help but conclude that this is the method of choice both for ease and for optimum results. This is certainly not accepted by most allergists in this country.

Summarizing, this is an excellently organized work presenting the literature of allergy in a very thorough and lucid fashion. It emphasizes a correlation of the principles of immunology as studied in chronic and acute infections with the immunology of the allergic conditions. The faults found in this book—the use of many unusual and newly coined terms and the overemphasis of the value of oral therapy—may well be disregarded by the critical reader in view of its general excellence.

Mass Miniature Radiography. A Practical Handbook. By R R Trull MC MA MD Wing Commander R A F V R H J Trenchard MB ChB MRCP Squadron Leader R A F and J A Kennedy MB BS MRCS Flying Officer R A F V R Foreword by Lord Dawson of Penn LC CVO KC B Cloth Price 8s 6d Pp 96 with 21 illustrations London J & A Churchill Ltd 1943

This book contains complete information for setting up and operating equipment for the making of miniature films of the chest. Chapters are devoted to administration, apparatus, processing and storage of films, viewing methods, interpretation, correlation of findings and consequent disposal of patients. The authors point out that the Canadian army has used full size x-ray films and that the Metropolitan Life Insurance Company of America has combined such films with fluoroscopy in mass survey work. The idea of photographing the image on a fluorescent screen on a photographic film was first attempted in 1896. However, it was not until 1934 that de Abreu of Brazil used it in making mass examinations. The authors describe two types of film now in common use, one 4 by 5 inches in size and the other approximately 1 inch square on a 35 millimeter film. They consider the former superior in technical excellence but prefer the 35 millimeter film for mass radiography because of greater speed with which exposures can be made. Attention is called to the use of these miniature films in the United States Army and Navy, and their value in the civilian population is emphasized. Their opinion as to the value of an x-ray film in diagnosis is expressed as follows: "Miniature films or large films are not generally speaking sufficient evidence on which to found a diagnosis. If they are so used the results are likely to be disastrous. Diagnosis must be based on a review of clinical, radiological and pathological evidence and it is essential that this fact be ever borne in mind. In other words, mass miniature radiography is a means of picking out those individuals who are in need of a full, clinical examination." This statement was formulated after the authors had made 150,000 examinations including the follow-up to final diagnosis of those discovered to have abnormalities on x-ray films. The conclusion of these authors with reference to diagnosis coincides with that of clinicians who are expert in chest diseases in this country.

The authors call attention to the extreme tiring of the eyes and the mental fatigue which results when viewing miniature films. They find that 350 to 450 films represent the extreme limit that any one can be expected to do in a day, and that one hour of continuous viewing is the maximum that should be attempted. Clinicians who are beginning this work should not attempt the reading of more than 60 films at one session. However as experience increases one can read about 150 to 200 films at one time without experiencing extreme fatigue.

In the chapter on interpretation of miniature films they say "In the ordinary way miniature films cannot be described as diagnostic. They should not be considered as showing more than an abnormality which requires a large film and other investigations to ascertain the nature of the lesion present. Consequently the report on a miniature film must usually be

limited to two alternatives. These alternatives are 'normal' and 'large film required'. The presence of a lesion should then be confirmed by a full sized x-ray film."

The authors point out that mass x-ray film inspection may also reveal evidence of nontuberculous infection such as abscesses, malignancy and fungous infection, as well as changes in the outline of the cardiac shadow. In the entire book nothing is said about the tuberculin test as a screen to determine who should have x-ray film inspection of the chest. This is probably because the authors assume that where they worked nearly 100 per cent of adults were infected with the tubercle bacilli. In this country where 50 per cent or less of adults are infected, the tuberculin test has extreme value. However, the reactors need other phases of the examination for tuberculosis. A film of the chest which shows no evidence of disease often gives the individual a false sense of security, and he sees little need for subsequent film inspection of the chest, whereas a tuberculin reaction informs him that he has a potential case of clinical tuberculosis, and even though the film of the chest at the moment is clear he is easily convinced that periodic films are important. This is a good book, and the reader should frequently refer to the statement on page 3 with reference to the disastrous results which may follow attempts to make diagnoses from x-ray films alone, regardless of the size of film used.

Release from Nervous Tension. By David Harold Fink, M.D. Cloth Price \$2. Pp 232. New York: Simon and Schuster, Inc., 1943.

It is, perhaps, inappropos to review this volume for a scientific journal, since at best it must be relegated to the seemingly endless and wearying stream of popular "expositions" of that most abused and long suffering branch of medicine, psychiatry. To begin with, the book's breathless Sunday supplement style will probably offend the literate reader, whereas the informed one will resent its assertive naïveté ("Human beings have no instincts"), its pretentious and often misleading pronouncements ("For sufferers from mental disease, Pavlov has sounded a veritable liberty bell. To cure sick nerves, the patient must be dehypnotized") and the frequent lapses into gross misinformation ("[The] nervous center of our emotional life is called the interbrain. Inspiration without expression leads to cell death within your brain"). Many of the "case histories," as the author indirectly admits, are obviously invented to suit the occasion, and even so reveal a superficiality of insight and interpretation that cannot but confuse and misguide the lay reader.

Fortunately, not all sections of the book are equally disappointing, since the basic theme of some chapters is that many bodily dysfunctions are the expression of emotional conflicts and tensions—a thesis quite in accord with the holistic principles of modern psychosomatic medicine. Conceivably, some readers may thus be induced to seek much needed psychiatric advice, although, unfortunately, most psychiatrists would be hard put to it to find the simple explanations and invoke the thaumaturgic cures described with such fervor in his own practice by Dr. Fink. Again, the author shows some appreciation of the dynamics of unconscious motivations, although he continually confuses them with a mysterious 'subconscious' which resides in the "interbrain." But here are the curealls recommended in the final chapters: a ten weeks course of verbalized, self-hypnotic "relaxation exercises," regressive and even compulsive "play" activities, Korzybskiesque (though not so accredited) "control" of "words that are triggers to action" and the inevitable autobiographic cost and credit "self analysis" designed to reveal hidden "complexes [which are] really conditioned reflexes." At the end of all this self-administered treatment the patient, according to the author, is ready for a "fresh start," which may involve sudden, untimed and thoroughly disruptive occupational, marital and social changes. All in all, it is difficult to imagine a set of recommendations potentially more dangerous for the ruminating, anxiety ridden, impulsive neurotic who, even under the most competent and individualized psychotherapy, is notoriously apt to misinterpret and misapply his physician's analysis and guidance. But perhaps this is less an indictment of Dr. Fink's book than a lament for the morbid activity of that portion of our population of neurotics that creates an apparently insatiable demand for this type of pseudopsychiatry.

Edward Tyson, M.D., F.R.S., 1650-1708 and the Rise of Human and Comparative Anatomy in England. A Study in the History of Science. By M. F. Ashley Montagu, Associate Professor of Anatomy, Hahnemann Medical College and Hospital Philadelphia. With a foreword by George Sarton. Memoirs of the American Philosophical Society, Volume XX. Cloth Price, \$5. Pp 488, with 56 illustrations. Philadelphia: American Philosophical Society, 1943.

When an American scientist gives the Croonian lecture before the Royal Society of London for Improving Natural Knowledge he is paid from an endowment fund secured after William Croone's death, 1684, by Edward Tyson of Bristol and London M.D., F.R.S., "founder of comparative anatomy in England," who laid the foundation on which was built Darwin's demonstration of animal evolution and the descent of man. Tyson was the first in England to institute the routine of systematic dissection and was one of the great protagonists of embryology, biochemistry and psychiatry. He "ranks with the immortals among anatomists" but has not been fully appreciated.

After the Puritan revolution in England of 1649 and after the restoration of 1660 some great spirits sought refuge from the fanaticism of religion, politics and scholastic philosophy in the direct study of nature. Inspiration had been given them by Gilbert, Bacon and Harvey, and for them the influence of tradition and authority had vanished. Their meetings for discussion founded the Royal Society. Among Tyson's friends in it were the crotchety Robert Hooke, the anatomic draftsman William Cowper, the selfless John Ray, Isaac Newton, Thomas Sydenham, Samuel Pepys and Robert Boyle. Tyson's contributions were many "preferring the language of artisans and countrymen to that of wits and scholars." Among the leading ones were the anatomy of the chimpanzee (pygmy), opossum, ostrich, lion, civet cat (Tyson's glands) and tapeworm. The publication of the first mentioned is "one of the outstanding landmarks in the history of science," Sarton.

Dr. Montagu makes these old times live again and makes these men our friends. We live with the bachelor Tyson from his boyhood days on the sea near Bristol to his death (from coronary occlusion?) aged 58 in London. He gives us their thoughts and their language and happily their quaint spelling: ostridge, pensil, phisitian, buigness, bruut, bloud, blew. One name may seem especially quaint to us, a Latin name Tyson gave to an American animal he dissected, "vipera caudivora" the rattlesnake.

It is very appropriate that this history of one of the early members of the London Society is published as a memoir of "The American Philosophical Society held at Philadelphia for Promoting Useful Knowledge." The form and presswork are beautiful. Dr. Montagu's work is so scholarly and sympathetic, so thoroughly and convincingly documented and illustrated that it deserves a place among the foremost American biographies of scientific men.

Regional Analgesia for Intra Abdominal Surgery With Special Reference to Amethocaine Hydrochloride. By Norman R. James, L.R.C.P. & S.D.A. Cloth Price, 6s. Pp 57, with 27 illustrations. London: J & A Churchill Ltd., 1943.

This book was written to increase the interest of surgeons and anesthetists in the use of regional methods of anesthesia in England. It is an excellent presentation of the value of anethame (amethocaine hydrochloride, or what is known in the United States as pontocaine hydrochloride) as an agent in producing prolonged anesthesia. The method of preparing the solution, its mixture with epinephrine and the equipment that is used are all described. Supplementary narcotics intravenously, administration of omnopon (pantopon) and the use of oxygen and anesthesia by inhalation and by use of bromurates are discussed. Thoracic nerve block is described, as is also spinal block, especially the posterior method of Kappas, infiltration of lines of incision and infiltration for suprapubic drainage, as well as for other purposes are described. The toxic effects and prophylaxis in relation to amethocaine hydrochloride are described. General operative technique is discussed. Cooperation between anesthetist and surgeon. Some suggestions in operative technique are suggested to facilitate the use of local anesthesia. Application of the method in various operations is described. A short index is included. This book is of size and will be of interest to surgeons and anesthetists.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT NECESSARILY REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

EARLY ABORTION, LATE ABORTION AND PREMATURE DELIVERY

To the Editor—What is the dividing line in time of gestation between an early and a late abortion? The other day a baby was born in this hospital after six months gestation breathed a few times and died. One of the members of our record committee said that this should be classified as a late abortion. Will you please tell us if this is correct?

Katherine Lehman R.R.L. Napa Calif

ANSWER—The following criteria are widely followed and employed as definitions for these terms in the Standard Nomenclature of Disease. Premature delivery is to be diagnosed if any two of the following criteria are present. 1 The length of the gestation is from twenty-eight to thirty-eight weeks. 2 The fetal size is between 1000 and 2500 Gm. 3 The fetal length is from 35 to 47 cm. Late abortion is to be diagnosed in the event of delivery of a previsible fetus if any two of the following criteria are present. 1 The length of the gestation is from twenty-two to twenty-eight weeks. 2 The fetal size is between 400 and 1000 Gm. 3 The fetal length is from 28 to 35 cm. Early abortion is presumed to have occurred if any two of the following criteria are present. 1 The length of the gestation is less than twenty-two weeks. 2 The fetal size is less than 400 Gm. 3 The fetal length is under 28 cm.

This classification is arbitrary and not entirely above criticism. It does not relate to stillbirth or live birth certification. Occasionally an immature live fetus of twenty-six or twenty-seven weeks gestation may survive and it would certainly be awkward for such a person to look back at his own history to find that he had been classified as a late abortion. It is probably better however to have such an unusual occurrence than to dislocate a series of otherwise satisfactory definitions in order to try to cover all contingencies.

PREGNANCY RESULTING FROM COITUS OR ARTIFICIAL INSEMINATION

To the Editor—A woman aged 28 had been married six years without pregnancy and had been trying to get pregnant by intercourse for about one year without result. Examination showed an enlarged cervix with mucous discharge, a crooked cervical canal and a definite uterine retro flexion. After treatment of the cervicitis with florquin suppositories and vinegar douches the condition improved somewhat. Five inseminations with the husband's seminal fluid found to contain a normal number of normal appearing sperms were done during a period of time extending from October 24 until January 15 of the next year, an attempt being made to choose a time during the latter part of the menstrual cycle. The last period was from January 22 to 29 just as expected but with slightly increased bleeding thereafter there were none and pregnancy was diagnosed definitely on May 4, being about three months along. The patient has had regular unguarded coitus during the time of the inseminations. The periods previous to the last one had been of normal character. The patient feels that this pregnancy is due to insemination. I am doubtful owing to the period following a week after the last insemination still circumstantial evidence points to insemination rather than normal coitus as being the cause. What would your impression be?

M.D. California

ANSWER—If all of the inseminations were carried out during the latter part of the menstrual cycle as implied in the query and the woman's menstrual intervals were of the usual twenty-eight to thirty day type, it is practically certain that the pregnancy was not due to the inseminations but to the normal coitus. The reason for this statement is as follows. As far as is known the majority of women ovulate only once a month and the ovum is expelled fourteen to fifteen days before the ensuing menstrual flow is to begin. An ovum lives for only about twenty-four hours, and unless it is fertilized within this time it dies. Spermatozoa are capable of fertilization for forty-eight to seventy-two hours. Therefore in order for pregnancy to take place, living spermatozoa capable of fertilization must be present in the genital tract for at most forty-eight hours before the ovum is expelled and for only about twenty-four hours after ovulation has taken place. Since the unfertilized egg is capable of fertilization for only twenty-four hours insemination of sperm in the latter half of the menstrual cycle is of no avail. If however, a woman's menstrual intervals are thirty-five or more days long, insemination at the twentieth or twenty-first day of the cycle can result in pregnancy. This is because

the ovum in such cases is expelled from the ovary on or about the twenty-first day of the cycle. In the determination of the day of ovulation, the preovulatory interval is of little significance. What is important is the number of days which elapse between ovulation and the ensuing menstrual flow, and this is usually fourteen to fifteen days.

DIAGNOSIS OF TYPE OF HYPERTENSION

To the Editor—A man aged 36 developed hypertension following an infarct of the lung. The history goes back to one year ago when he was seized with severe pain in the lower right quadrant of the abdomen. Acute appendicitis was suspected. The consulting surgeon found the patient in a shocklike condition with low blood pressure and feeble pulse, and sweating profusely. Renal colic was the tentative diagnosis. Urinalyses revealed many red cells in the sediment. White cell and differential counts were normal. Twenty-four hours later pain in the lower right quadrant of the abdomen was still present, muscle spasm was evident and there was an increase in the white cell count. Appendectomy was performed under nitrous oxide anesthesia. The pathologist's report was 'catarrhal appendix'. The patient was free from pain until the seventh postoperative day, when lodgment of an embolus in his right lung resulted in an infarct. Recovery followed in six weeks without any pulmonary residual. Two months later he returned to work but complained of pulsating headaches, nausea and anginal pains on exertion. The blood pressure at this time was 170/120 (right arm). The symptoms persisted for three months and on reexamination he was found to have unequal blood pressure in his arms. After rest in bed for one month his average blood pressure was 145/110 (right arm) and 120/80 (left arm). In the erect position the blood pressure in both arms was 150/110. Other clinical findings during this time were as follows: grade 1 arteriosclerosis of the retinal vessels; electrocardiographic evidence of minimal myocardial damage and sinus arrhythmia; normal blood chemistry (sugar, chlorides, nonprotein nitrogen, creatinine); normal hemoglobin values; white blood cell count and differential count negative Wassermann and Kahn reactions; normal results from urinalysis and culture of urine; normal results from the sedimentation test, the urea clearance test, the phenolsulfonphthalein test and the concentration dilution test; normal x-ray appearance of the skull, the chest, the kidney, ureter and bladder, the heart and the aorta; normal intravenous pyelograms; x-ray evidence of four devitalized teeth previously treated by apicectomy and root canal medication and showing no foci of infection. Other findings were psoriasis (chronic, minimal, nonprogressive) and a postnasal drip. The cold pressor test was within normal limits. Neuropsychiatric examination was noncontributory. During preparation for the intravenous pyelograms the patient was given 1 cc of posterior pituitary injection of twice U.S.P. concentration intramuscularly. The symptoms previously complained of returned and persisted for three hours. At present the patient's blood pressure after prolonged rest in bed will be as low as 120/80. Limited activity in the erect position soon results in a blood pressure of 150/110. Anginal pains and nausea occur at infrequent intervals. During one such episode the blood pressure in his left arm for three consecutive readings was 135/110, 140/100 and 125/90. The blood pressure in the right arm was 150/120. The nausea disappeared in about fifteen minutes and the blood pressure in both arms was found to be 150/110. Can the blood pressure be explained as a Goldblatt phenomenon? What is the significance of the variation in blood pressure in the arms and legs? Is it possible that he suffered renal infarcts as well as a pulmonary infarct during his initial illness with the result that renal circulation is impaired sufficiently to cause hypertension? Any suggestions will be appreciated. M.D., South Dakota

ANSWER—The absence of preexisting hypertension must be presumed since previous levels are not recorded. In spite of the reported differences of blood pressure in the two arms, the right arm showing higher levels while the patient is recumbent, this feature must be minimized, since equal levels (150-110) occur in the erect position and this level seems to be basic on activity especially since x-ray and physical examinations indicate that no aneurysm is present. If available, cutaneous temperature and oscilometer readings taken when significant variations were present would aid in determining if true circulatory inequality exists.

A degree of paroxysmal hypertension appears to be present. This may be caused by adrenal tumors (difficult to diagnose) or by postural hypertension, especially with a mobile kidney. It is true that in the vast majority of cases of renal prolapse or mobile kidneys no hypertension or Goldblatt mechanisms will exist but there is an increasing number of authenticated cases in which such conditions or malposition of kidneys, with the pelvis not directed truly medially in which case the renal vessels may be compressed or angulated in reaching the pelvis will result in hypertension of the Goldblatt type.

In the case cited it would be impossible for renal infarction to have occurred directly from the primary (presumably pelvic) source but the remote possibility of a secondary source (from the lung following primary infarction) cannot be disregarded. Apparently the right kidney was the seat of trouble (many red blood cells) in the first attack and it may be the site of unilateral renal disease.

Another intravenous pyelogram taken in the standing position may reveal an unsuspected renal prolapse. It is significant that the pressures are higher when the patient is in the upright position than when he is recumbent. Should such a prolapse be found a well fitted girdle or a renal belt with pads to keep

the kidney in place may be tried. If this is unsuccessful and elevations of pressure persist, nephropexy is justified since otherwise persistent and progressive essential hypertension may be anticipated.

TREATMENT OF CONGENITAL SYPHILIS WITHOUT INTRAVENOUS INJECTIONS

To the Editor—A girl aged 15 years has interstitial keratitis. I treated her in infancy for syphilis but the parents stopped the treatments before she was cured. She has had no treatment in the meantime. She weighs 230 pounds (104 Kg) and it is impossible to find any veins in which to give intravenous therapy. Will you please outline the treatment this patient should have? All treatment will have to be intramuscular or by mouth.

M D, Iowa

ANSWER—In view of the impossibility of administering intravenous treatment to the patient a girl aged 15 with congenital syphilis and interstitial keratitis, the best plan of treatment would be initially with induced tertian malaria during which the patient is allowed to have ten to twelve paroxysms of fever, followed immediately on its termination by bismuth arsenophosphate (bismarsen) administered intramuscularly twice weekly in alternate buttocks in a dosage of 0.2 Gm to a total of twenty injections in the course. On completion of the bismarsen course, bismuth subsalicylate in oil should be given intramuscularly for eight to twelve weeks in a dosage of 0.2 Gm the injections being given at weekly intervals. Potassium iodide should not be used.

Further than this it is impossible to plan without knowing the results of the suggested treatment on the interstitial keratitis. More treatment must be given, but its character will depend on the therapeutic result obtained.

ROENTGEN IRRADIATION FOR MASTOIDITIS AND OTITIS

To the Editor—Has the x-ray radiation treatment of acute mastoiditis and otitis media ever been used in the majority of ear clinics in the country? What is the present status of this treatment?

Nathan Sedofsky, M D, Oteen, N C

ANSWER—X-ray radiation therapy for acute otitis media and acute mastoiditis has never been widely used in the majority of ear clinics in this country. There has been no fundamental change in opinion as to the way these diseases are to be handled. It is no doubt true that here and there individuals have tried x-ray therapy. In properly selected cases gratifying results have been obtained.

It would be impossible however, without a poll of all the major clinics in the country, to know how many of them have used x-ray treatment in the conditions named and to what extent they have employed it. Judging by one large community it is not used extensively nor is it the treatment of choice.

In early cases x-rays may be used properly empirically and experimentally. It is precisely this type of case that yields so well to sulfonamide therapy, however, and which has a high incidence of natural recovery. There can be no useful outcome in debating the merits of special therapy under these circumstances. Able practitioners working under proper controls and using good judgment may try at times any reasonable method of therapy.

NORMAL PYELOGRAM IN PRESENCE OF IMPAIRED RENAL FUNCTION

To the Editor—A woman was admitted to the urologic service because of numerous red and white cells in the urine. In the course of a routine examination the resident said he found a large kidney on the left side in addition to a few white and red blood cells in the urine. An intravenous pyelogram was of little assistance in making a diagnosis as little dye appeared on the left side. Cystoscopy revealed a normal bladder and ureters, the latter were readily catheterized for a distance of 25 cm. The urinary outflow was normal on both sides. A functional test was normal on the right, the dye appearing in six minutes. No dye appeared on the left side in twenty-five minutes. A retrograde pyelogram was made, 10 cc being injected on both sides with no pain. A roentgenogram shows normal outline of both kidneys. Would you kindly explain the poor function of the left kidney in view of the normal retrograde pyelogram?

M D, New York

ANSWER—Failure of visualization of the renal pelvis on one side occasionally is observed in the excretory urogram for which there is no adequate explanation. In a few of these cases, when a subsequent excretory urogram is made after an interval of several weeks or months the visualization will have become normal for no apparent reason. In many cases failure of visualization can be explained by temporary obstruction in the ureter, often a small ureteral calculus, which is nonopaque and is not visualized in the plain roentgenogram. Such a calculus might

also be the cause of the red and white cells which appeared in the urine in the case in question. The fact that the ureteral catheter when introduced met with no obstruction would not exclude a calculus. In fact, the failure of secretion of dye from that kidney in the presence of secretion of fluid would tend to corroborate the hypothesis of reflex irritation or short obstruction caused by intraureteral blockage. Such obstruction may be sufficient to interfere with renal function but still cause no visible deformity in the outline of the renal pelvis or ureter. In most of these cases of ureteral blockage the outline of the kidney in the plain roentgenogram appears somewhat larger than that on the other side, apparently due to congestion.

There may, of course, be some kind of intrarenal lesion present. An infarct or some other type of cortical lesion might also cause failure of secretion of the dye without visible deformity in the pelvic outline. Repeating the differential functional tests and the excretory urograms at intervals would be of considerable interest.

POSSIBLE EFFECTS OF EPINEPHRINE AND EPHEDRINE ON CUTANEOUS TESTS WITH ALLERGIC SUBSTANCES

To the Editor—A patient with hay fever is relieved by an ephedrine-cyt-l capsule. Are the cutaneous tests interfered with if this capsule is used immediately preceding the tests?

H F Kohler, M D, Tacoma, Wash

ANSWER—Swineford and Grove (*J Allergy* 8 475 [July] 1937) have pointed out that the maximum effect of an injection of epinephrine on the size of cutaneous tests occurs within fifteen to thirty minutes and is gone in an hour or less. They therefore believe that it is not necessary to postpone these tests longer than one hour after a single therapeutic injection. When the patient is receiving frequent injections of epinephrine, however, especially if given in oil, cutaneous tests are certain to be lessened in size and should not be performed at that time.

There is no definite report in the literature on the effect of ephedrine on cutaneous tests, but since ephedrine acts in a similar fashion to epinephrine it too almost certainly diminishes the size of cutaneous tests. This is especially important with patients who take ephedrine more or less continuously.

It would be wise to avoid both ephedrine and epinephrine for at least twenty-four hours before the tests are carried out.

EPIDIDYMITIS FOLLOWING STRAIN

To the Editor—Could you give me the pathology of a condition which I have been seeing frequently in the past two years but which I do not find described in textbooks on urology? It occurs only in men usually doing heavy work, who give a story of having felt a sharp pain in the lower part of the abdomen on one side or the other while straining as in lifting a heavy weight, the pain frequently radiating down the spermatic cord to the testis. The following day the spermatic cord and sometimes the epididymis is also swollen, hard and tender. Sometimes only the upper pole of the epididymis is involved. Needless to say these are cases in which no evidence of gonorrhea is found. The condition being apparently traumatic in origin. Pain and tenderness vary in severity, and the condition gradually subsides in about a few weeks' time. As far as can be made out by physical examination it appears to be the vas deferens itself which is thickened and tender. Torsion begins with a severe pain which lasts for a considerable period. The cord is always swollen, indurated and tender. In fact, the swelling seems to progress from above downward as frequently the cord is only the upper part of the epididymis are involved. I have seen many cases of this condition that I regard it as a clinical entity.

M D, Puerto Rico

ANSWER—As nearly as can be determined from the description, this is an acute epididymitis. The history is typical, namely pain in the lower part of the abdomen on one side or the other and frequently radiating down the spermatic cord to the testis, followed by changes in the epididymis the epididymis being tender, hard and swollen. The fact that there is no evidence of gonorrhea is irrelevant.

Most urologists believe that when a patient develops an epididymitis he has infection in the seminal vesicle. This infection may or may not be gonorrheal in origin. As a matter of fact most cases of seminal vesiculitis and chronic prostatitis are nongonorrheal in origin.

Acute and chronic epididymitis that fit into the category described in textbooks on urology. How much of this condition is ascribed to the onset of the condition to the lifting of a heavy weight is open to question. If persons do not have a previous infection in the vesicles and lift a heavy weight, it is not clear how it happens.

The second possibility is torsion of the spermatic cord or torsion of the testis, but the description given does not fit with torsion of the spermatic cord. This condition has been written up a good many times in the literature within the past ten years.

SPIROCHETAL JAUNDICE

A REPORT ON FIFTY-NINE CASES INCLUDING TWO
CASES OF LEPTOSPIRA CANICOLA INFECTION

FRANCIS E BRUNO MD

CARL J W WHELEN, MD

AND

J R SNAVELLY MD

NEW ORLEANS

Spirochetel jaundice has been reported from practically every country in the world.¹ Despite its universality the number of cases reported in North America appears to be disproportionately less than that reported from continental Europe. In the interval 1924-1937 808 cases were diagnosed in the Netherlands.¹ Between 1924 and 1932 263 proved cases were found in France.² In the Netherlands the diagnosis was established in 374 cases between 1924 and 1938, and there were at least 248 cases in Great Britain between 1922 and 1939.³ In contrast, up to 1940 Stiles and Sawyer⁴ state that they were able to collect only 73 authentic cases from North America, with half as many additional cases on which laboratory data were regarded as inadequate. Larsen⁵ states that up to August 1941 98 cases of spirochetel jaundice had been observed in Puerto Rico and in fourteen states and the District of Columbia in the United States.

Many authors⁶ feel that the condition is not rare in this country. Why then is the disease so infrequently diagnosed? In this article we wish to show that spirochetel jaundice has been overlooked in the past to emphasize certain interesting features of the disease which have come under our observation and to point out some of the problems in differential diagnosis which occurred in 15 cases that were recently observed at Charity Hospital.

It is most certain that vectors harboring leptospira are not lacking in the United States. Raven,⁷ during the months of May and June 1941, found positive agglutinations for leptospiras in 28 per cent of serums collected from dogs in Philadelphia. Serums of dogs from rural communities in Pennsylvania showed 38.1 per cent positive agglutinations. In these animals data relative to clinical history were not available, so that it was

impossible to tell whether a clinical or a subclinical infection had preceded the seropositive reactions. Serologic tests performed on supposedly normal dogs in San Francisco and northern California gave positive reactions in 34 per cent.⁸ In this study 14.3 per cent of dogs from a rural community showed latent infection. Blood of dogs from Louisiana, Nebraska, New York, Pennsylvania and Virginia were reported as giving positive agglutinations for *Leptospira icterohemorrhagiae*.⁹

Rats have been found to be infected to no less an extent in the United States. Sampling of 467 rats in San Francisco yielded renal leptospira by dark field examination in 176 instances (35 per cent). Meyer and his associates⁸ state that renal leptospira infection has been definitely established in Washington D C 10 per cent, in Nashville, Tenn., 10 per cent, in New York 17.2 to 21.9 per cent, in Albany, N Y 40 per cent, in Baltimore, 7 per cent, in Chicago, 3 to 5 per cent, in Rochester, N Y, 38 per cent, and in Detroit, 16 per cent.

Recently, examination of mine water and muck revealed leptospiras morphologically indistinguishable from *Leptospira icterohemorrhagiae* in a single mine in Alabama where 14 human cases of spirochetel jaundice occurred in a period of two and a half years.¹⁰ Non-pathogenic saprophytic spirochetes occur in natural waters all over the world.¹ Although there is a disagreement concerning this possibility, apparent transformation of nonpathogenic strains to virulent forms after culture or animal passage has been described.¹¹

It might be supposed that the murine strains which have been found in such a large proportion of American rats were nonpathogenic. However, Langworthy and Moore¹² have demonstrated that strains in New York State were virulent.

In addition to the rat and dog, it has been shown that leptospirosis may occur in field mice, cats, pigs, foxes and horses.² Although leptospiras have not been demonstrated in these animals in the United States, it may be assumed, with the proportion of infected dogs and rats that has been demonstrated, that leptospirosis is present in these animals in at least a moderate percentage.

It has been pointed out by Ashe³ that North Americans are not immune. The occupations which are described as being commonly affected in Europe are in the main the same for the reported American cases. It is our impression that typical cases of spirochetel jaundice have always been present in Louisiana if not

the entire United States. Ideal situations for exposure exist for the trappers and fishermen and for the rice and cane field workers of southern Louisiana. Older clinicians have told us that in their opinion numerous cases of spirochetal jaundice have been confused with yellow fever in the past. In this connection it is an interesting commentary that Stimson¹³ discovered, in 1905, "spirochetes" in the organs of a Louisianian dying from what was thought to be yellow fever. Such mistakes are not difficult to make because clinically and pathologically¹⁴ spirochetal jaundice and yellow fever may be quite similar.

Ashe believes that the clinical manifestations are not well enough known in this country for the disease to be considered in the differential diagnosis. Other authors¹⁵ feel that the diagnosis is chiefly dependent on the laboratory and that the fault lies in the fact that too few American laboratories are equipped to establish the diagnosis.

An occupational history has usually been present in the reported cases. In most instances a history of moist, damp or wet environment is obtainable. Frequently immersion accidentally or intentionally, in a polluted stream has resulted in the disease. Consequently, occupations commonly encountered in the disease are those of sewer workers, trapped coal miners, canal workers, fish workers, rice-field workers and cane cutters.

The disease is a severe one and is typically characterized by an acute onset which is associated with chills, headache and extreme muscle pain with nausea and vomiting. The majority of patients are prostrated. The amount of fever is variable, ranging from 99 to 104 F. Abdominal pain localized in the epigastrium or right upper quadrant is frequently a prominent feature of the disease. In the latter part of the first week jaundice and enlargement of the liver usually become apparent. Conjunctivitis and injection of the pharynx have been described by many authors. A moderate leukocytosis is usually present. Renal function is usually affected, oliguria, anuria, albuminuria, casts and cells may occur and there may be retention of the nitrogenous factors in the blood. A hemorrhagic tendency or anemia is apparent in about half the cases. In seven to thirteen days there is improvement in the general symptoms and convalescence begins. In some instances a febrile relapse may occur at the beginning of the third week. Meningeal signs may be present.¹⁶

The diagnosis is essentially dependent on the laboratory.⁹ The leptospiras can be found in the blood in the first stage (seven to thirteen days). Immune bodies can be found between the twelfth and the seventeenth day and are present in increasing concentration after this time. The organisms may be found in the urine after the second or third week. Inoculation of guinea pigs or hamsters after the technic described by Ashe² may facilitate diagnosis either from the blood or from the urine in the appropriate period. We wish to emphasize here the important work of Schultz,¹⁷ who demonstrated the ease with which the inexperienced investigator may be misled in his interpretation by "pseudospirochetes" observed in dark field preparations of blood.

CHARITY HOSPITAL CASES

Stimulated by the characteristic findings shown by 4 white male patients¹⁸ studied in the Tulane Medical Service at Charity Hospital during August and September 1941, an attempt was made to ascertain how many cases of spirochetal jaundice had been overlooked in the interval Sept. 1, 1939 to Sept. 1, 1941. Accordingly the charts of 463 patients whose discharge diagnoses could possibly have been confused with spirochetal jaundice were reviewed. Of this number 54 records were sufficiently suggestive to warrant recall of the patients for an agglutination test. Blood from 40 patients of this group was sent to the National Institute of Health. Three of the serums were found to have a diagnostic titer of agglutinins against *Leptospira icterohemorrhagiae*. The case histories of these patients follow in brief. Comparison with the other cases on a chart which outlines the salient features of the 15 cases recently observed at Charity Hospital show that the following 3 cases are typical. It will be noted that these cases did not constitute an epidemic but occurred over a period of two and one-half years and in widely separated parts of southern Louisiana.

F. H. (case 5), a white man aged 58, a laborer, admitted to Charity Hospital on May 7, 1941, complaining chiefly of jaundice, had been noted as being icteric six days prior to admission. Four days later anorexia developed and later he became nauseated and vomited at frequent intervals. The vomitus was "streaked with red." Physical examination revealed that he was poorly nourished, asthenic and "yellow as a canary." He was acutely ill but afebrile. The sensorium was cloudy. There was old, clotted blood present about the mouth. The mucous membranes were soft and bleeding. The teeth were carious, and oral hygiene was poor. The pharynx was injected. The heart and lungs were normal. The remainder of the physical examination was negative except for small areas of hemorrhagic extravasation into the skin at various points over the body.

The red blood cell count was 3.5 million, the white blood cell count was 7,000 with 93 per cent polymorphonuclear leukocytes. The platelet count was 310,000. Urinalysis revealed 1 plus albumin and 1 plus bile. The blood urea nitrogen was 42.7 mg per hundred cubic centimeters. The icterus index on admission was 195 units and rose to 300 units.

The patient was discharged on May 30 with the diagnosis of acute catarrhal jaundice. He was subsequently recalled and blood submitted to the National Institute of Health on April 2, 1942 was reported as positive against *Leptospira icterohemorrhagiae* in a dilution of 1:1,000.

C. B. (case 10), a white man aged 39, a farmer, admitted to Charity Hospital on July 31, 1940, suffered from "indigestion" after every meal one week prior to admission, with abdominal pain and belching. On the following day fever developed and he had two chills which were associated with pain in the extremities, backache and a severe headache. The following day it was noticed that he was jaundiced. In the next few days he noticed that his urine had become red. On admission he was well oriented and presented well developed jaundice. The only positive physical conditions he exhibited were carious teeth and slight tenderness in the right upper quadrant.

The red blood cell count was 1.81 million. A urinalysis revealed hemolysis beginning at 0.36 and completed at 0.24. Urinalysis revealed 2 plus bile. The icterus index was 160.

The patient was discharged on August 30 with a diagnosis of acute catarrhal jaundice. He was recalled on January 11, 1942 and agglutinins were found against *Leptospira icterohemorrhagiae* in a dilution of 1:1,000.

B. O. (case 11), a Negro youth aged 19, a porter, admitted to Charity Hospital on July 25, 1941 had been ill for several days with a headache and generalized ache and pain.

prior to admission. In a short while he became nauseated and vomited. Four days later his family noticed that his scleras were yellow. Because of the persistent nausea and vomiting the patient came to the hospital.

On admission his temperature was 99 F. The scleras were icteric and there were subconjunctival hemorrhages. There were a few palpable submaxillary nodes. A few crepitant rales were present at the base of the right lung. The liver was palpable two fingerbreadths below the costal margin. The remainder of the physical examination was negative.

The red blood cell count was 3.9 million. The white blood cell count was 15,700 with 82 per cent polymorphonuclear leukocytes. The prothrombin time was 73 per cent of normal. Urinalysis revealed 3 plus albumin and a trace of bile. Bile stained casts were present. The blood urea nitrogen was 77.7 mg per hundred cubic centimeters. The icterus index was 50. On August 16 the patient was discharged with a diagnosis of acute catarrhal jaundice. The patient was subsequently recalled, Feb. 3, 1942, and agglutinins were found to be present in the patient's serum against *Leptospira icterohemorrhagiae* in a dilution of 1:10,000.

We believe that the following conditions have been most commonly confused with leptospirosis: catarrhal jaundice, typhus fever, malaria, acute yellow atrophy, toxic hepatitis, amebic hepatitis, yellow fever and obstructive jaundice with associated cholangitis. In the first world war many cases of spirochetal jaundice¹ were described as occurring in French, Italian, British and German troops. Undoubtedly if trench warfare is resorted to in this war numerous cases will develop in rat-infested trenches which are frequently contaminated with stagnant water. It has been shown¹⁰ that leptospires can live for a period longer than three weeks in stagnant water that is slightly neutral or alkaline.

BRONCHOPULMONARY FEATURES

A point which deserves further emphasis is the ease with which the disease can be confused with acute pneumonia. The sudden onset with chills, fever, cough and expectoration of sputum, which is often blood tinged combined with physical and radiologic evidences of pulmonary infiltrations, can be indistinguishable from atypical bacterial, virus or influenzal pneumonia. The diagnosis is especially difficult in the anicteric or preicteric case. The development of icterus in such a severely ill patient, especially if it is associated with myalgia, hemorrhagic tendencies and appropriate urinary findings, should strongly suggest spirochetal jaundice. If jaundice appears several days after the institution of sulfonamide therapy, the diagnosis of toxic hepatitis as a complication of either pneumonia or sulfonamide therapy may be easily entertained and the true condition overlooked. Just this sequence of events occurred in 4 of our cases.

An illustrative case is the following:

H. G., a man aged 34, a warehouse workman, became suddenly ill with fever, chills and headache on Aug. 18, 1941. He began to expectorate blood tinged sputum within a few hours and was treated for pneumonia by a physician who gave the patient sulfathiazole. This medication was discontinued on the fifth day of his illness because of the appearance of well defined jaundice. During this time there were repeated chills and fever to 104 F, and the patient was disoriented at times. Urine was noted to be very dark brown, but at no time was oliguria observed. The patient was admitted to the hospital on the ninth day, at which time his pulse was 120, respirations 24 and blood pressure 130/20.0. Save for deep icterus and a barely palpable tender liver, there were no positive physical manifestations on admission. The white blood cells numbered 12,400 with 85 per cent polymorphonuclear

leukocytes. The urine showed 4 plus bile and urobilinogen to a dilution of 1:10, the icterus index was 333 and the blood urea nitrogen was 80. For four weeks in the hospital the patient's condition ran a continuously febrile course with chills and fever to 104 F. Repeated small transfusions were given, and near the middle of the fourth week of illness 250 cc of blood from a patient who had recovered from spirochetal jaundice two years previously was given. No dramatic results followed, but the patient's temperature gradually fell until near the end of the sixth week he became afebrile and definitely convalescent. On the twenty third day of illness the patient's serum agglutinated *Leptospira icterohemorrhagiae* to 1:100,000 and on the thirty-fourth day to 1:1,000,000.

CENTRAL NERVOUS SYSTEM FEATURES

The meningeal form of leptospirosis was discussed in detail by Walch-Sorgdrager.¹ He states that it is characteristic of the meningeal form that there is nothing to suggest spirochetal jaundice. There are variable degrees of meningeal signs and symptoms in the cases reported. The spinal fluid is usually under increased pressure, it is nearly always clear, it is weakly positive for albumin and the number of cells is increased. Blood agglutination tests are positive. Forty-three per cent of our patients had a severe headache, and, of the 14, 4 had delirium or a severe degree of restlessness. Spinal puncture in 2 cases was negative. Patient 12 was disoriented and had a convulsion followed by weakness of the right hand. Lumbar puncture was not performed in this instance.

VARIATION IN SERUM TITER

In the majority of our patients the titer of agglutinins increased as convalescence occurred. In 1 case (L. D., case 14) the titer dropped from 1:1,000 to 1:100 in twenty-one days. In another (A. E., case 9) agglutinations on blood were positive in a dilution of 1:30,000 in October 1939. When the patient was recalled on Jan. 19, 1942 the agglutinations were negative. As can be seen from the following brief report, this history is typical for spirochetal jaundice.

A. E., a Negro youth aged 19, a laborer in the rice fields and a trapper in the off season, admitted to Charity Hospital Oct. 10, 1939, became acutely ill five days prior to admission. He was seized with epigastric pain which shifted to the right upper quadrant. This was associated with chills, fever, nausea and vomiting. There were severe muscle pains and headache. On admission the patient had herpes and conjunctival hemorrhages and he became definitely jaundiced. On admission the pharynx was hyperemic. The base of the right lung was dull to percussion and tubular breathing was thought to be present. The liver was palpable. The white blood cell count was 18,300 with 86 per cent polymorphonuclear leukocytes. Blood urea nitrogen was 22.4. The icterus index was 300 units. Urinalysis revealed 3 plus albumin, 3 plus bile, 3 to 5 red blood cells and white blood cells with an occasional bile-stained cast per high power field. The electrocardiogram was interpreted as showing evidence of myocardial damage with a slightly long PR interval and QT interval. Roentgenograms of the chest were negative. Serum sent to the National Institute of Health was reported as positive in a dilution of 1:30,000 in October 1939. The patient was recalled and serum taken on Jan. 19, 1942 was sent to the National Institute of Health and was reported as negative.

This shows that the power of agglutination can be lost in spirochetal jaundice and suggests that perhaps immunity may likewise be lost.

LEPTOSPIRA CANICOLA INFECTIONS

The serum in 2 of our cases (12 and 15) agglutinated against the *Leptospira canicola* in a dilution of 1:10,000 and 1:1,000,000 respectively and against the *Leptospira icterohemorrhagiae* in a dilution of 1:1,000 and

¹⁰ Davidson, L. S. P., Campbell, R. M., Rae, H. J. and Smith, J. *Wells Disease*. Brit. M. J. 2: 1137 (Dec. 22) 1934.

1,000,000 respectively. Ashe in his comprehensive review on spirochetel jaundice states that up to May 1941 only 1 human case due to *Leptospira canicola* had been reported in the United States. Though our patients had no knowledge of contact with jaundiced dogs or other animals, it is interesting that in the three months prior to the illness of patient 12 local veterinarians⁹ had observed at least 9 cases of icterus in dogs. Unfortunately we were unable to secure blood for agglutinations or tissues for examination from these jaundiced animals. Lester and his co-workers¹⁰ in their investigation of an epidemic of spirochetel jaundice occurring in mine workers attempted to determine the possibility of dogs serving as a reservoir of infection. The examination of blood and tissue sections in jaundiced dogs provided by local veterinarians failed to demonstrate leptospira. Walch-Sorgdrager states that the canicola disease has certain special characteristics. Severe symptoms were uncommon and jaundice was

and hyperemic. The oropharynx was injected. The lungs were clear and resonant. There was slight enlargement of the heart. The rate and rhythm were regular. No murmurs were heard. The liver was just barely palpable. The remainder of the physical examination was not worthy of note. The red blood cell count was 4,900,000, the white 13,600, with 65 per cent polymorphonuclears. Urinalysis showed 3 plus bile and an occasional white cell. The icterus index was 129 units. The blood urea nitrogen was 69.6 mg. per hundred cubic centimeters. On March 31 agglutinations performed by Dr. Elliston Farrell were positive in a dilution of 1:300 against *Leptospira icterohemorrhagiae*. A sample of serum sent to the National Institute of Health on April 14 was reported as being positive in a dilution of 1:10,000 against *Leptospira canicola* and 1:1,000 for *Leptospira icterohemorrhagiae*.

HEMORRHAGIC DIATHESIS AND GASTRO-INTESTINAL FEATURES

One of the essential pathologic features of spirochetel jaundice is a hemorrhagic diathesis which presumably results from a local toxic effect of the spirochete on the capillary wall. The prothrombin time of the blood may or may not be abnormal. Six of our patients had prothrombin determinations during the height of their illness. Four of these had an obvious hemorrhagic diathesis and the prothrombin determinations were 75 per cent, 83 per cent, 73 per cent and 100 per cent of normal, respectively. The determination of 100 per cent normal was made on patient 8, who had severe melena and hematemesis. Two patients who showed no evidence of a bleeding tendency had readings of 60 per cent and 95 per cent respectively. This hemorrhagic tendency may cause minute hemorrhages in the skeletal muscles, lungs, liver, stomach, pancreas, adrenals, peritoneum and spleen. In the more severe cases purpura, hematuria, hematemesis and melena may be present. Fully one half of our patients showed hemorrhagic phenomena. These manifestations consisted of purpura, petechial and subconjunctival hemorrhages, bleeding mucous membranes, hematemesis and melena and 1 patient had a uterine hemorrhage.

As a consequence of these factors and notably from hemorrhage into the intestinal wall and an inflammatory reaction in the duodenum and around the ampulla of Vater, severe gastrointestinal symptoms may develop. All but 1 of our patients complained of abdominal pain. Rigidity of the abdominal wall was present in 4 cases and in 9 cases nausea and vomiting were present for a varying length of time. Patient 8 had melena and hematemesis and required five blood transfusions. Patient 13 entered the hospital with severe abdominal pains, rigidity, nausea and vomiting. The leukocyte count was 50,000. The physical examination indicated an acute abdominal emergency, but the nature of the onset and course of the disease and our previous experience with spirochetel jaundice were the determining factors in a conservative policy. Twelve hours later the acute symptoms had subsided and the leukocyte count had fallen to 30,000, and the patient went on to uneventful convalescence. In connection with this case it is of interest to point out the experience of White and Prevost. A cholecystogastrostomy was done on their patient two months after the onset of spirochetel jaundice and the gallbladder was found to contain hemorrhagic material which on dark field examination was positive for *Leptospira*. Another case reported by Gaines and Johnson²¹ on operation showed an intramural obstruction

Fig. 1—Section of kidney of O. D. Arrows indicate *Leptospira*.

rare. Meningeal symptoms occupied a prominent place in 4 of the 12 cases reported by him. Because of the rarity of *Leptospira canicola* disease, case 12 will be described in brief.

E. R. (case 12), a white man aged 63, a night watchman, admitted to Charity Hospital March 25, 1942, stated that two weeks prior to admission he had an infection of the upper respiratory tract with mild malaise for a few days and only a slight cough. About ten days prior to admission his temperature was 102° F. The local physician who was called said he had a "touch of pneumonia" and gave him white powders and a cough medicine. His fever subsided in one or two days. In one week the patient's wife noticed that he had a yellowish tinge to his skin. At this time his urine frequently. He was voiding small amounts of urine frequently. He made satisfactory progress until the day of admission, when his wife noticed that he was cloudy mentally. Shortly after this he had a mild convulsion. He regained consciousness in a few minutes but was mentally hazy on admission.

Physical examination revealed that he was well nourished and was uniformly jaundiced. There were numerous excoriations over the abdomen and back. The scleras were icteric.

of the ductus choledochus consequent to inflammation of the duodenum and the impullus of Vater. Appreciation of the various aspects of the gastrointestinal manifestations of this disease are of great importance in the differential diagnosis during the acute stage.

CARDIAC AND ELECTROCARDIOGRAPHIC FEATURES

Symptoms and findings referable to the heart are not uncommon in our experience. The German literature cites numerous instances of pathologic changes in the heart consisting of myocardial necrosis, fibrous pericarditis, infarction and vegetative endocarditis. Descriptions of similar complications have not appeared in the American literature to our knowledge. In our 1 case that came to autopsy (case 4) scattered petechial hemorrhages were observed in the endocardium. Microscopic examination showed fibrinous exudate on the epicardium with collections of lymphocytes in the underlying connective tissue. The myocardium showed scattered areas of fragmentation and there were areas containing free red blood cells in the stroma.

We have observed the following clinical conditions during the acute stages of the disease: gallop rhythm, pericardial friction rub, enlargement of the heart, severe sinus tachycardia and premature beats. Most of these findings disappeared during convalescence. Electrocardiograms were taken on 5 of our patients and among the significant findings noted were prolongation of the QT interval, defective auriculoventricular conduction, low T waves, blocked auricular beats and prolonged PR intervals. Electrocardiograms taken during convalescence showed a gradual return to normal.

Fig 2—Section of heart of O. D. Note transverse fragmentation of myocardial fibrils. Interstitial edema and hemorrhage are also present.

A brief report of our fatal case referred to is given here. The pathologic changes in this case have been described in detail by Harris.¹⁴

O. D., a white man aged 39, a dirty hand, noted the sudden onset of his illness on Sept. 14, 1941 associated with severe pains in the muscles of his forearms, legs and back. Later in the day a shaking chill was experienced, and his temperature was found to be 101 F. Shortly thereafter he began to vomit greenish material, and by evening he had begun to experience

a dry hickling cough. This course continued for five days, during which time much smaller amounts of urine than normally were passed, and the patient became progressively more exhausted with chills and high fever. He was admitted on the fifth day of his illness when a definite icterus was observed. Physical examination was otherwise negative save for a tender

Fig 3—Section of liver of O. D. Note central area of necrosis.

enlarged palpable liver. The white blood cell count was 15,000 with 97 per cent polymorphonuclear leukocytes, the urine showed 3 plus albumin, numerous red blood cells, many granular casts and 4 plus bile. Blood urea nitrogen was 16.1, dextrose 143 and the icterus index 110. A chest film revealed no abnormalities. While in the hospital, the patient became steadily more toxic, his temperature went higher and he voided very little urine. On the eighth day a pericardial friction rub was heard. Death occurred on the ninth day of his illness, when his temperature was 103 F. No urine was passed in spite of heroic measures to produce diuresis.

Autopsy revealed, among the essential findings, jaundice, petechial areas over the chest and ecchymotic areas over the parietal peritoneum. The liver was enlarged. Microscopic sections of the liver showed considerable disorganization of the arrangement of the liver cells which occurred in groups of 2 or 3 cells rather than in continuous cords. These groups were interspersed with clumps of lymphocytes. The kidney sections showed a diffuse infiltration of lymphocytes between the glomeruli. The latter were small and showed large capsular spaces. Many endothelial lined spaces filled with blood were observed in the medulla and to a lesser extent in the cortex. Levaditi stains of the kidney showed many leptospiras. When the pericardial cavity was opened some fibrinous exudate was noted on the epicardium in the region of the right auricle. Microscopic examination showed fibrinous material with collections of lymphocytes in the underlying connective tissue. The myocardium showed areas of fragmentation. Free red blood cells were evident in areas of the stroma. Blood taken from the patient post mortem agglutinated *Leptospira icterohemorrhagiae* in a titer of 1:500.

COMMENT

We are inclined to agree with Ashe and his group that a clinical diagnosis of spirochetal jaundice is feasible, but we would like to add the qualification "with assurance only in typical cases." We feel that many cases are typical and will be missed unless the condition is considered and the proper laboratory studies are car-

ried out We wish to suggest that in any acute infectious condition in which agglutinations for other diseases are negative tests for leptospirosis be made

As Welch-Sorgdiager has pointed out, the clinical symptoms of diagnostic significance are

1 An acute infectious disease with acute onset, fever, headache and prostration 2 Severe myalgia appearing spontaneously and on pressure in the thigh, calves and back 3 Signs of liver damage 4 Signs of kidney damage 5 Leukocytosis 6 Epidemiologic information—immersion, occupation We feel that if any four of these features are present the diagnosis of spirochetel jaundice should be strongly entertained

SUMMARY AND CONCLUSIONS

There are some factors which might explain the increasing incidence of reported cases of human leptospirosis in North America It has been pointed out that spirochetel jaundice has been present in Louisiana since at least 1905 Salient features of 15 cases have been observed at Charity Hospital over a period of two and one-half years Interesting aspects are encountered in the differential diagnosis of these cases There is a high incidence of gastrointestinal symptoms and abdominal crises The similarity of spirochetel jaundice in its early phases to pneumonia makes it possible for the condition to be mistaken for hepatitis secondary to pneumonia or sulfonamide therapy Symptoms and clinical signs referable to the heart and the electrocardiogram have been encountered

OCCIPITOPOSTERIOR POSITION

JAMES P. HENNESSY, MD

NEW YORK

The occipitoposterior position is perhaps the most common and important abnormality in the mechanism of vertex presentations, occurring in approximately 25 per cent of all such presentations Its management has long been a matter of discussion Although the literature on the subject is voluminous and facts of some value have been derived from it, there will undoubtedly be many more contributions, for there will always be a posterior

The occipitoposterior position is probably much more common than is generally supposed I am convinced that many prolonged labors supposedly occipitoanterior were occipitoposterior in the beginning The reported incidence varies greatly Tweedy and Wrench¹ reported 121 cases in 15,167 deliveries (0.8 per cent), Williams,² 11.3 per cent in 5,000 cases, Scott,³ 14.04 per cent in 1,000 consecutive cases, Piper⁴ 17.1 per cent, Danforth,⁵ 25.1 per cent in 1,131 private deliveries In an earlier paper⁶ I reported 500 cases of occipitoposterior position in 3,966 deliveries, an incidence of 12.6 per cent D'Esopo⁷ noted that 19 per cent of all vertex presentations engaged in the posterior position In our series of 5,105 deliveries in St Ann's Maternity Hospital, including both private and general services, there were 600 cases of occipitoposterior position (11.76 per

cent) Detailed statistics of these cases will be found later in this paper

In vertex presentations the occiput, as a rule, lies at a lower level in the pelvis than the sinciput and consequently rotates forward even in cases in which

Chart 1—Correlation of length of first stage of labor with type of pelvis in cases of occipitoposterior position in two hour intervals

it was posterior in the beginning In a small proportion of cases the back is posterior at first and flexion is not complete, consequently the sinciput is as low as or even a little lower than, the occiput As a result the sinciput tends to rotate forward, the face lying behind the pubes, and the occiput is carried into the hollow of the sacrum

Incomplete flexion of the head, and hence posterior rotation of the occiput, is more common when the occiput is primarily directed backward Herman⁸ explains this tendency as follows Extension of the head in occipitoposterior presentations comes about in two

Chart 2—Correlation of length of second stage of labor with type of pelvis in cases of occipitoposterior position in fifteen minute intervals

ways (a) because the axis of the uterus and of the pelvic brim is concave behind, (b) because the greatest diameter of the head is behind the center The child must accommodate its attitude to the space in which it lies When the axis of the upper part of the fetal pelvic canal is concave behind then the child is

lies in front the spine will be bent and the abdominal surface, which is behind may be concave. If the position of the child is such that the abdomen lies in front then accommodation to the cavity can be obtained only by some extension of the spine. If this extension is enough to bring the occipitospinal joint in front of the line along which the propelling force acts, this force will, unless opposed, produce full extension of the head. When the head enters the brim with the occiput anterior the biparietal diameter corresponds almost exactly with one or the other oblique diameter of the pelvis when there is room for it. If however the occiput is posterior the biparietal diameter must fit into a diameter of the pelvis which is posterior to and smaller than the oblique diameter. As a result the occiput is retarded, producing a varying degree of extension.

As to the cause of primary occipitoposterior position opinions differ, but many authors⁹ agree as to the deviations from normal of the bony pelvis. Thoms¹⁰ mentions the relative or the actual diminution of the transverse diameter of the inlet and Caldwell and Moloy¹¹ state that this type of deformity, as exhibited in their "android" pelvis, necessarily tends to cause posterior engagement. Our experience has shown that the narrower the anterior pelvis the higher the percentage of posterior positions. Many authors recognize definite pelvic contraction as a cause of posterior posi-

tion with anterior positions. On an average it lasts from two to four hours longer in primiparas and from one to two hours longer in multiparas. I believe that this delay occurs during the stage of expulsion and that in the majority of cases rotation occurs spontaneously if labor is allowed to continue long enough.

Chart 4—Correlation of the left and the right occiput anterior position (LOP and ROP) with number of birth

but we have tried to spare our patients and shorten the second stage of labor by correcting this abnormality. How this should be done depends on the individual operator. Every obstetrician who has had a large experience with this position is apt to have rather definite ideas as to its treatment, and probably the procedure in which he is most adept is the best for his use.

In determining whether intervention may be necessary, careful palpation of the ischial spines is most important. If they are unduly prominent there will be more midplane contraction and the chances of long rotation are considerably decreased. A warning that manual rotation, use of forceps or version may be required. X-ray findings may be misleading for the X-rays do not always show clearly the size, height and thickness of the ischial spines and the narrowing of the midplane. If the biparietal diameter is narrow, posterior position may be anticipated early in labor and operative intervention may be instituted under the most favorable circumstances. Delay in anterior rotation of the head as it descends in the pelvic cavity is definitely the result of cephalopelvic disproportion or of that pelvic asymmetry which materially diminishes the space in the fore pelvis. With the relatively greater amount of space in the posterior pelvis, the law of accommodation necessitates a posterior position of the occiput, that is descent in the line of least resistance.

In cases with no satisfactory progress it is our rule to recheck, owing to the probability of a posterior position.

Chart 3—Correlation of delivery by cesarean section with type of pelvis. This operation was performed in 17 (2.8 per cent) of the 600 cases of occipitoposterior position.

tion. The etiologic importance of deflection of the head is often mentioned, but deflection in turn depends on such pelvic asymmetry as disturbs the equality of pressure on the ends of the occipitospinal lever (Cosgrove). Other important causative factors to consider are the posture of the fetus in utero and weak labor pains (poor muscle tone). The latter also applies to the abdominal muscles, particularly in lax or pendulous abdomens. The association of weak labor pains with a deficient pelvic floor is found in a large percentage of multiparas. Here the elements which normally bring about flexion and internal rotation are absent, and the occiput is likely to remain posterior.

The occipitoposterior position is not in itself a pathologic condition, but it may become so because of persistence caused by the factors mentioned. Posterior positions are likely to be a cause of difficult labor, owing to the fact that the head is usually extended when difficulty is encountered. Naturally, therefore, if there is any pelvic disproportion the labor is increasingly prolonged. Whether or not subsequently the position is corrected by anterior rotation, labor is more tedious.

Chart 5—Correlation of spontaneous anterior rotation with type of pelvis in the 232 cases of occipitoposterior position in which it occurred.

4 In the narrow fore pelvis the true conjugate is of average length, also with a forward promontory of the sacrum there are more occiput transverse presentations

5 In a series of 600 consecutive cases of occipito-posterior position at St Ann's Maternity Hospital New York the gross fetal and neonatal mortality was 1 per cent. The fetal mortality, therefore, was no greater than in occipitoanterior positions

6 Parity and age apparently are not factors in this complication

7 Large size of the baby per se is not the cause of posterior positions, it is a factor only when associated with pelvic deviations from the normal

8 The occipitoposterior position need no longer be dreaded, as nearly all cases can be dealt with successfully even if anterior rotation should fail to occur spontaneously

PREVENTION OF EXPERIMENTAL RABIES

TREATMENT OF WOUNDS CONTAMINATED BY RABIES
VIRUS WITH FUMING NITRIC ACID, SOAP
SOLUTION, SULFANILAMIDE OR
TINCTURE OF IODINE

HOWARD J. SHAUGHNESSY, PH.D.
AND
JOSEPH ZICHIS, PH.D.
CHICAGO

Prevention of rabies by local treatment of bites inflicted by rabid animals has occupied the attention of practitioners of the healing art from at least as early as the first century A. D. Celsus¹ at that time and Galen² in the next century advised cauterization with a hot iron. The latter also suggested that the wound be incised and drawing medicine applied in order to maintain a running ulcer for at least forty days.

Between that time and the eighteenth century many other methods of treatment were employed. Many of these were based on mysticism or empiricism, often in conjunction with the actual cautery. Soon after the eighteenth century began, cauterizing agents other than the hot iron came into use. Silver nitrate and burning with gunpowder were employed. The first to advocate the use of nitric acid seems to have been Dr. Samuel Danforth.³

Little information is available in the literature in regard to the efficacy of these methods of treatment. Most of the results have been presented in the form of case reports. Since physicians now know that about 65 per cent of those bitten by rabid animals escape infection,⁴ this kind of proof means little when only 1 or 2 cases are cited.

Scant proof has been offered to show the value of the various types of local treatment that have been

applied to wounds contaminated with rabies virus experimentally. Babes⁵ studied the value of the thermocautery in dogs and rabbits. He inflicted wounds on the faces of 10 dogs and 15 rabbits and then contaminated the wounds with fixed rabies virus. The wounds of 8 dogs and 13 rabbits were deeply cauterized at different intervals, and the remaining 2 dogs and 2 rabbits served as controls. Three of the 8 treated dogs and 4 of the 13 treated rabbits did not develop rabies while all of the controls died.

In the experiment in which he used rabbits all of the 7 animals whose wounds were cauterized more than twenty-five minutes (twenty-five to sixty minutes) after contamination developed rabies. In his experiment with dogs all but 1 of the 5 animals whose wounds were treated after twenty-five minutes developed rabies. The dog that escaped infection was 1 of 2 treated after an interval of twenty-four hours.

In 1899 Follen Cabot⁶ published his studies on the prevention of experimental rabies by local treatment of wounds with fuming nitric acid. Since his publication is widely quoted as a basis for the use of fuming nitric acid for the treatment of wounds inflicted by rabid animals on human beings, the technique that he followed is stated in full.

A portion of medulla taken from a rabbit dead from laboratory rabies was beaten into an emulsion composed of 1 part of medulla to 5 parts of sterile water. Of this emulsion 1 cc. was injected with a hypodermic needle into the outer and upper part of the thigh of a guinea pig. The hair was closely cut, and the point of the needle introduced one-fourth of an inch, at right angles, into the region of the sciatic nerve. The injected virus was left undisturbed for twenty-four hours at the end of which time an incision half an inch long was made over the seat of puncture, exposing the nerve. The tissue in the wound surrounding the point of puncture was carefully swabbed out and the cautery applied. The animal meantime being anesthetized with chloroform.

For each of his experiments Cabot divided his animals into four groups. Group 1 was treated with fuming nitric acid; group 2 with the thermocautery; and group 3 with silver nitrate. In group 4 the wounds were swabbed out with dry absorbent cotton and left open. Each group had its own set of control animals. Of the guinea pigs that were treated with fuming nitric acid 91 per cent did not develop rabies, against 15 per cent of the controls. The results with the actual cautery were equally striking, as 70 per cent of the treated animals and only 11 per cent of the controls escaped infection. In the experiments with silver nitrate 55 per cent of the treated animals did not become infected compared with 16 per cent of the control animals. Thus one per cent of the guinea pigs whose wounds were only swabbed out with cotton and 16 per cent of the controls did not develop rabies.

Poor⁷ reported the results of a single experiment in which he used fuming nitric acid to treat wounds that had been contaminated with rabies virus. He made an incision on the back of the neck of each guinea pig and cut the subcutaneous tissues on either side of the wound in several places with scissors. The wound was

contaminated with street virus and then the edges were brought together with adhesive plaster. Twenty-two hours later they were opened and fuming nitric acid was applied. Twenty guinea pigs were used in this experiment and of this number 12 were treated and 8 served as controls. Five of the treated animals did not develop rabies whereas all the controls succumbed.

It is difficult to evaluate the results of these experiments. With the exception of Cabot's⁹ experiments the studies were conducted with comparatively small numbers of animals. The experimental procedures used by these investigators were varied and in some instances were quite unlike the natural mode of infection and application of therapy. Cabot's methods especially may be criticized in the latter regard. The application of cauterizing agents to the region of the exposed sciatic nerve might have damaged the nerve sufficiently to prevent progression of the virus along its fibers. Possibly this explains, at least in part, why Cabot obtained such good results. Obviously, however, such a method of treatment which may involve the destruction of many nerve trunks could not be employed in the prevention of human rabies.

Rosenau⁸ wrote in his textbook:

Experiments under my supervision (unpublished) indicate that practically all guinea pigs may be saved by prompt application of nitric acid that its effectiveness decreases with time but that it is still partially protective up to forty-eight hours. No other substance gives equally good results. Strong germicides such as carbolic acid are not reliable. Nitrate of silver is valueless. Formalin and the actual cautery are not effective.

Nitric acid on account of its diffusibility and penetration is almost specific for rabies.

The experiments referred to by Rosenau have not been published; consequently it is not possible to analyze his results. It would be of interest, however, to know how many substances other than those he mentioned were tried by him and how he determined the diffusibility and penetration of nitric acid applied to wounds of this character. It should be pointed out that Rosenau's and Cabot's observations conflict in respect to the use of silver nitrate and the actual cautery but that they are in complete agreement in regard to the effects of fuming nitric acid.

The clinical and the experimental evidence cited in the preceding paragraphs do not, in our opinion, establish the value of fuming nitric acid in the prevention of rabies. Yet it appears that on the basis of these reports most public health and medical authorities at the present time recommend that bites inflicted by rabid animals be treated with fuming nitric acid. Cauterization with fuming nitric acid produces many undesirable reactions. Its application to wounds is painful and bacterial infections may result because of its destructive action on tissues. Usually healing is slow after its use and severe scarring may follow. If the acid is applied to deep wounds, contractures may result or periosteal and bony tissues may be damaged. Consequently, physicians are reluctant to apply fuming nitric acid to bites of rabid animals, especially when the bites are deep and badly lacerated or when they are inflicted on the face. Gowen's¹⁰ survey of the actual practice in Illinois bears this out. He showed that fuming nitric

acid was used to treat only about 28 per cent of the cases in which wounds inflicted by presumably rabid animals were given any form of local treatment.

In view of these facts we decided to investigate more thoroughly the effect of fuming nitric acid in the prevention of rabies by applying it to wounds that were contaminated experimentally with rabies virus. In addition we compared the value of soap solution and tincture of iodine with that of fuming nitric acid. We also studied the effect of packing the wounds with sulfanilamide after they had been treated with soap solution.

METHODS AND MATERIALS

Virus.—In these studies it was desired to infect either guinea pigs or mice with rabies virus in such a manner as to simulate as closely as possible the mode of the infection resulting from a bite of a rabid animal. Since natural rabies is caused by an infection with rabies street virus and since most of the animal bites are deep enough to reach subcutaneous and muscle tissues, attempts were made to obtain a strain of street virus that would be infectious for these animals on inoculation into these tissues. Twenty-eight strains of street viruses were isolated from brains of dogs that had died of the natural disease. The isolations were made by preparing a 10 per cent suspension of the brain of each dog and by injecting 0.5 and 0.15 cc intramuscularly and 0.15 and 0.03 cc intracerebrally into guinea pigs and mice respectively. Usually 2 guinea pigs and 4 mice were given an injection by each route and with each specimen. The intramuscular inoculation was made into the gastrocnemius muscle.

Only 5 of these 28 strains produced rabies by intramuscular inoculation. Each of these 5 strains infected about 50 per cent of the guinea pigs and mice in the first passage. By the intracerebral route of injection, all of the strains were infectious for both guinea pigs and mice, producing about 96 per cent mortality. A diagnosis of rabies was made in the test animals by detecting Negri bodies in smear preparations of the brains of those that died.

Only those viruses that were infectious by intramuscular injection were employed in the experiments. Each virus was passed once either in guinea pigs or in mice by the intramuscular route before it was used to infect the experimental animals. In attempts to infect a larger number of animals under the experimental conditions it was found that these strains did not produce rabies consistently. The rates of infectivity varied from 5 to 50 per cent in the control mice and from 1 to 80 per cent in the control guinea pigs. Their virulence could not be enhanced or maintained by serial intramuscular passages either in guinea pigs or in mice. Four strains lost their infectivity by the intramuscular route after two passages and one after four. Consequently these studies could not be successfully conducted with any of these strains of viruses. They were employed in a few of the preliminary studies but a fixed rabies virus was used in the main experiments.

After testing the virulence of several strains of fixed rabies viruses it was found that one strain, S-1, consistently infected guinea pigs and mice by the intramuscular route of inoculation. S-1 virus was fixed for rabbits, and it was maintained in them by serial intracerebral passages. Before it was used to inoculate the animals in the experiments it was passed once through guinea pigs by intramuscular injection except in experiments 16, 17 and 18 in which rabbit brain virus was employed. Its virulence after the first passage in guinea pigs was such that 0.5 and 0.1 cc of a 1 per cent suspension of an infected guinea pig brain produced rabies in 100 per cent of the guinea pigs and mice respectively. The virus was inoculated in the muscle tissues of the left hindleg and the animals died within ten days after the injection. The minimum lethal dose of S-1 virus for mice by the intracerebral method of inoculation was about 0.03 cc of a 10^{-6} dilution.

In the experiments each guinea pig was given an injection of 0.2 cc of either a 10 or a 20 per cent suspension of the

virus. The virus suspensions were prepared from approximately equal portions of the brains of at least 2 guinea pigs which had died after intramuscular injection of S-1 virus. Only brains that were free from bacterial contamination and had not been stored longer than five days at about -5°C were used. The suspensions of virus were made in hormone broth.

Inclusion bodies were found in the brains of guinea pigs and mice that died from infection with S-1 virus. Some of these bodies were spherical and others oval. They were about the size of Negri bodies with the exception that about 25 per cent of the spherical type were much smaller. When the bodies were stained by Seller's method their peripheries were dark blue; the bodies themselves were pink and the typical dark blue granules seen in Negri bodies were absent. The presence of these inclusion bodies was not considered diagnostic for rabies.

Animals.—Guinea pigs weighing from 300 to 450 Gm were employed in the main experiments. Albino Swiss mice each weighing about 20 Gm, were used in the preliminary studies and in the virus neutralization tests. The sexes were about equally represented in both the guinea pigs and the mice. The animals were kept in individual cages to prevent fighting, cannibalism and cross infection. In the experiments the animals were kept under observation for thirty-five days after inoculation. Thereafter the surviving animals were released and about 90 per cent of the female and about 15 per cent of the male guinea pigs were used for breeding purposes. Under such an arrangement more than 65 per cent of the released guinea pigs were observed for about one year. The longest incubation period that was noted in the guinea pigs inoculated with S-1 rabies virus was fifteen days; the average being about seven days.

Methods of Inflicting the Wounds and Inoculating Them with Rabies Virus.—The procedures of inoculation were designed to approximate as closely as possible the mode of the infection caused by a bite of a rabid animal. Three such methods were employed. The site selected for the wound in each case was the muscular tissue on the back of the neck, slightly anterior to the shoulder blades. The hair was always clipped from the site of inoculation, and aseptic technique was observed in all of the methods.

Method 1. A rat tooth forceps was dipped into a 20 per cent virus suspension and then clamped on the neck muscles of the animal. By this procedure the wound was contaminated at the same time that it was inflicted. The amount of the virus suspension transferred by the forceps in a single dip could not be accurately determined. It was estimated, however, that about 0.05 cc of the suspension was planted in the wound. The wound inflicted in this manner contained three punctures and in the course of treatment it was necessary to treat each puncture separately. For inoculation of guinea pigs this procedure was unsatisfactory because the skin of these animals owing to its thickness could be punctured by the teeth of the forceps only with difficulty. Although method 1 probably simulates most closely the natural mode of infection it could not be used in experiments with guinea pigs.

Method 2. This is a modification of the technique employed by Cabot¹⁰ and Poor.¹¹ Only guinea pigs were inoculated by this method. Each animal received 0.2 cc of a virus suspension in the muscle tissues in the back of the neck, slightly anterior to the shoulder blades. A 22 gage hypodermic needle, 3 mm long was used. The needle was inserted 3 mm deep at right angles to the surface of the body. Thirty minutes after the inoculation an incision about 12 mm long and about 9 mm deep was made exposing the locus of the virus injected and the needle track. The open wound was then treated.

Method 3. In this procedure an incision was made with a scalpel in the muscles on the back of the neck, slightly anterior to the shoulder blades in each guinea pig. The incision was about 12 mm long and about 6 mm deep. Immediately after the wound was inflicted, approximately 0.2 cc of a virus suspension was deposited in it from a syringe with an 18 gage blunt needle. Following the inoculation the wounds were slightly irritated with the tip of the needle.

Treatment of Animals Inoculated with Rabies Virus.—Fuming nitric acid, 20 per cent aqueous solution of soft soap,¹² tincture of iodine and powdered sulfanilamide were used to treat the wounds of the animals after they were inoculated with rabies virus. The application of the nitric acid was made by means of a glass rod drawn out to about 15 mm in diameter and 40 mm in length. This glass applicator was dipped in fuming nitric acid to the depth of about 10 mm and then applied to the wound. The clotted blood was removed from the wounds before the acid was applied. The irrigation with the soap solution was carried out with either 20 or 50 cc syringes fitted with 16 gage hypodermic needles 65 mm long. The wounds were irrigated under the pressure produced by the application of the full force of the hand to the plunger of the syringe. A small hole was drilled in the bottom of a 250 cc beaker through which the needle was inserted into the beaker. By holding the beaker in an inverted position over the wound of the animal it was possible to carry out the irrigation without allowing the spray to endanger the operator. The volume of the soap solution that was used is stated in reference to each experiment. The iodine was applied with a cotton swab on a wooden applicator. The methods of treatment with sulfanilamide are described in detail in the protocols of experiments 17 and 18.

The application of the fuming nitric acid to the wound caused severe burns and extensive scarring in most of the animals. The wounds healed slowly, requiring about twenty-eight days for complete healing. Consequently it was not possible to apply any more of the acid than could be picked up by one dipping of the applicator without causing death. The treatment with the soap solution, the tincture of iodine or the sulfanilamide did not cause any apparent toxic effects. The wounds healed much sooner than those treated with the fuming nitric acid and scarring was minimal. In each method of treatment the wounds were allowed to heal without being bandaged.

Methods of Diagnosing Rabies.—Since the clinical symptoms shown by guinea pigs and mice that develop experimental rabies cannot be considered definitely pathognomonic, laboratory methods were employed to establish the diagnosis of rabies in the animals that died. Two such methods were used. In those experiments in which the animals were inoculated with street rabies virus a diagnosis of rabies was established by the detection of Negri bodies in the brain tissue. The brain smears were prepared and stained for Negri bodies by Seller's method.¹³ In most of the experiments in which the animals were inoculated with S-1 fixed rabies virus the diagnosis of rabies was confirmed by the neutralization test.¹⁴ This test which was made only on representative animals was conducted as follows. One part of a 1:100 dilution of the virus infected guinea pig brain was combined with two parts of antirabic serum. The mixture was incubated at 37.5°C for one hour. During the incubation period it was thoroughly shaken every fifteen minutes. Then 0.03 cc of the mixture was injected into each of at least 3 mice by the subdural route. The test was controlled by using normal rabbit serum in place of the antirabic serum. In addition the brains and heart bloods of representative animals that died in each experiment were studied culturally for bacterial infection. When contamination was encountered the pathogenicity of the organism was determined by animal inoculation.

EXPERIMENTS

The preliminary experiments were conducted with the five strains of rabies street viruses which were isolated in our laboratory and which were found to be infectious for guinea pigs and mice by intramuscular inoculation. Four hundred and seventy-five mice and 75 guinea pigs were used. The mice were inoculated by

method 1 and the guinea pigs by methods 1, 2 and 3. From 5 to 50 per cent of the control mice developed rabies. In the control guinea pigs that were inoculated by method 1 the mortality was about 1 per cent and in those inoculated by the other two methods the mortality ranged from 15 to 80 per cent. In addition a

large number of the treated mice died in which a diagnosis of rabies could not be established. These deaths were attributed to the small size of the animals which involved exposure of a relatively large percentage of their body surfaces to the burning and toxic effects of fuming nitric acid, soap solution or tincture of iodine. In view of these results it was apparent that these studies could not be successfully conducted with either mice or our strains of street viruses. Consequently the work with mice and the street viruses was discontinued and the subsequent experiments were conducted with the S-1 fixed rabies virus and guinea pigs.

EXPERIMENTS 1 TO 6—The guinea pigs in these experiments were treated about thirty minutes after they were inoculated with rabies virus. Two hundred and twenty five guinea pigs were used, and they were distributed among the experiments as shown in table 1.

In each experiment the guinea pigs were inoculated with S-1 rabies virus by method 3. An incision was made in the muscles on the back of the neck slightly anterior to the shoulder blades in each animal and then 0.2 cc. of a 10 per cent suspension of the virus was deposited in the wound. If hemorrhage had occurred, the clots of blood were removed before treatment was begun. The fuming nitric acid was applied to the wounds by carefully probing them with the glass applicator after dipping it in the acid. A cotton swab was used for the application of the tincture of iodine. The wound of each animal treated with the soap solution in experiments 1 to 4 was irrigated with about 60 cc. of the soap solution while in experiments 5 and 6 about 120 cc. was used. The control guinea pigs were inoculated by the same procedure but their wounds were not disturbed after the inoculation with virus.

A diagnosis of rabies was established in representative guinea pigs that died in each experiment by means of the neutralization test with antirabic serum. The heart bloods and brains of representative animals in each experiment were studied culturally and pathogenic bacteria could not be found.

The results of experiments 1 to 6 show (table 1) that 89 per cent of the guinea pigs that were treated with fuming nitric acid, 93 per cent of those treated with soap solution and 90 per cent of those treated with tincture of iodine, compared with 37 per cent of the control animals, did not develop rabies. The results of treat-

ment with tincture of iodine compared favorably with those obtained with fuming nitric acid and with soap solution. They are however, less conclusive because a smaller number of animals were treated with it. Since the application of tincture of iodine to open wounds causes discomfort and in some instances chemical burns, it was decided to limit further studies with it.

As shown in these experiments (table 1) the application of fuming nitric acid, 20 per cent solution of soft soap or tincture of iodine to wounds about thirty minutes after they were inoculated with rabies virus was of decided value in preventing rabies. It is not always possible, however, to treat human beings or animals within thirty minutes after they have been bitten by a rabid animal. For this reason it was desired to determine what effect these agents would have when applied two or six hours after the animals were inoculated with rabies virus.

EXPERIMENTS 8 TO 12—In these experiments the guinea pigs were inoculated with S-1 rabies virus by method 3 and they were treated about two hours after inoculation.

Two hundred and eighty guinea pigs were employed, and they were distributed among the experiments as shown in table 2. Each animal received 0.2 cc. of a 20 per cent suspension of the virus. The control animals were inoculated with the virus by the same procedure but they did not receive treatment.

The experiments were conducted in the same manner as experiments 1 to 7 except that approximately 80 cc. of the soap solution was used to irrigate the wound of each animal that was treated with the soap in experiments 8 and 9 and about 200 cc. in experiments 10, 11 and 12.

The rabies virus used in these experiments was identified by the neutralization test with antirabic serum. The test was performed only on representative animals from each experiment. In addition cultural studies were made of the brains and heart bloods of representative guinea pigs from each experiment and no bacteria could be found.

As shown in table 2, in experiments 8 to 12, 81 per cent of the guinea pigs that were treated with fuming nitric acid, 85 per cent of those treated with the soap solution, 60 per cent of those treated with tincture of iodine and 26 per cent of the control animals showed

* The numerator is the number of guinea pigs that did not develop rabies; the denominator the number of guinea pigs used.

no evidence of infection with rabies virus. The results of these experiments show that the application of fuming nitric acid, soap solution or tincture of iodine to the wounds of guinea pigs two hours after they were inoculated with fixed rabies virus was of definite benefit in preventing infection. The treatment with tincture of iodine was less effective than that with either of the other two substances. As in the previous experiments

however, a much smaller number of animals were treated with tincture of iodine. Consequently a fair comparison of the results cannot be made. These results also show that treatment with either fuming nitric acid or soap solution was just about as effective when it was instituted in two hours as when in thirty minutes. The slightly lower percentage of survivors among the animals treated two hours after inoculation is probably of no significance since the percentage of survivors among the controls is also smaller in these experiments.

EXPERIMENTS 13, 14 and 15—The guinea pigs in these experiments were treated six hours after they were inoculated with rabies virus. Sixty guinea pigs were used in each experiment and they were divided into three groups of 20 each. The wound of each animal was inoculated with 0.2 cc of a 20 per cent suspension of S-1 virus by method 3. The fuming nitric acid was applied to the wounds in the same manner as in the previous groups of experiments. The wound of each animal treated with soap was irrigated with about 200 cc of the solution.

In these experiments (table 3) 63 per cent of the guinea pigs treated with fuming nitric acid, 67 per cent of those treated with the soap solution and 35 per cent of the controls did not develop rabies. The diagnosis of rabies in representa-

tive animals from experiment 14 was established by the neutralization test. The brains and heart bloods of representative guinea pigs from each experiment were studied culturally and bacterial contamination could not be detected.

The results of these experiments show that either fuming nitric acid or soap solution was of pronounced benefit in preventing rabies even when applied in six hours, although considerably less effective than when it was applied in two hours or thirty minutes.

As in the two previous groups of experiments here again the results of treatment with the soap solution were apparently slightly better than those obtained with fuming nitric acid, although the differences are not statistically significant.

EXPERIMENT 16—In this experiment it was desired to repeat as closely as possible the technique employed by Cabot⁶ and Poor.⁷ The guinea pigs were inoculated as described in method 2, 0.2 cc of a 20 per cent suspension of S-1 virus being injected into the muscle tissues on the back of the neck slightly anterior to the shoulder blades of each animal. About thirty minutes after the injection an incision was made as previously described, and the animals were treated immediately thereafter. The control guinea pigs were inoculated by the same procedure but they were not given any treatment after the incision was made.

Sixty guinea pigs were employed in this experiment. Twenty were treated with fuming nitric acid, 20 with soap solution and 20 were used as controls to determine the virulence of the virus. The fuming nitric acid was applied as in the previous

experiments, and about 100 cc of the soap solution was used to irrigate the wound of each guinea pig.

Fifty per cent of the guinea pigs that were treated with fuming nitric acid, 60 per cent of those that were treated with soap solution and 15 per cent of the control animals did not develop rabies. Brain tissues and heart bloods of representative guinea pigs were cultured and no bacteria could be detected.

The results of experiment 16 are in agreement with those reported by Poor.⁷ Also they are in general agreement with the results reported by Cabot⁶ although in his studies a much larger percentage of the guinea pigs that were treated with fuming nitric acid escaped infection. Possibly this difference may be attributed to the variation in the technique used in the inoculations and treatment.

EXPERIMENT 17—Soap solution and sulfanilamide¹³ were employed for treatment in this experiment. Each guinea pig was inoculated with 0.2 cc of a 20 per cent suspension of S-1 rabies virus by method 3. About thirty minutes later the wound of each animal was irrigated with 100 cc of soap solution, then sponged dry and packed with 0.5 Gm of powdered sulfanilamide. In each case immediately following treatment the wound was clipped together with metal clips. The control guinea pigs were inoculated by the same procedure but their wounds were clipped together without treatment.

Sixty guinea pigs were used in this study. Treatment was given to 30, and the other 30 served to control the virulence of the virus. Ninety per cent of the treated animals, compared with 20 per cent of the controls, did not develop rabies. Cultural studies were made of the heart bloods and brains of representative guinea pigs that died and bacterial contamination was not observed.

The results of this experiment are in agreement with those of our first group of experiments in which treatment was carried out only with soap solution showing that the sulfanilamide apparently did not influence the results one way or another.

EXPERIMENT 18—Each guinea pig in this experiment was inoculated with 0.2 cc of a 15 per cent suspension of S-1 virus by method 3. The treatment was carried out exactly as in experiment 17 except that the wounds were not irrigated with the soap solution. Before the sulfanilamide was applied, each wound was carefully and thoroughly swabbed out with cotton swabs that had been soaked in soap solution. At least four swabs were used in treating each wound.

Twenty-eight guinea pigs were used in this experiment. Of this number 14 received treatment and 14 were used as controls. Seventy-nine per cent of the animals that received treatment and 36 per cent of the controls did not show evidence of rabies. Cultural studies of the heart bloods and brains of the animals that died did not reveal any bacterial contamination.

These results show that the type of treatment employed here was considerably less effective than the type used in experiment 17. Although a comparatively small number of animals were used in this study, the results indicate that irrigation of the wounds with soap solution is much more effective in preventing rabies than cleansing the wound with cotton swabs that had been soaked in the soap solution. Here again the results indicate that the application of sulfanilamide to the wounds did not help to prevent rabies.

COMMENT

In these studies it was not possible to duplicate in every respect the natural mode of infection with rabies virus as represented in bites of rabid animals. The natural disease resulting from a bite of a rabid animal is caused by the rabies virus that is present in the saliva. It was not possible for us to employ a saliva

13 The sulfanilamide was supplied by E. R. Squibb & Co., N. J.

virus however because of the many difficulties involved in its procurement. Neither were we successful in our efforts to isolate from brain tissues of dogs that died of natural rabies a virus which would infect either guinea pigs or mice with any degree of consistency by intramuscular inoculation. For this reason our experiments were conducted with a fixed rabies virus which was found to cause the disease consistently by intramuscular inoculation.

A good deal of confusion exists in the literature regarding the infectivity of street and fixed rabies viruses by intramuscular inoculation. Investigators seem to be in agreement that a fixed virus is less infectious by this route. Marie¹⁴ Pasteur and his co-workers¹ and Genevray and Dodero¹⁵ have shown however that certain strains of fixed viruses do produce rabies in animals when inoculated intramuscularly. Little information is available on the infectivity of fixed viruses in man. Athas and Franca¹⁶ Franca¹⁵ Bireggi¹ and Remlinger¹⁰ cited cases in which death followed antirabic treatment with vaccine that apparently contained living virus. On the other hand Remlinger¹⁰ and Wissokowicz⁹ pointed out that people have been inoculated subcutaneously and intravenously with fixed rabies viruses without becoming infected. As to natural rabies, Cornwall⁴ stated that about 35 per cent of human beings bitten by rabid dogs die of rabies and Hutyna and Marek²¹ reported that about 30 per cent to 40 per cent of dogs bitten by rabid animals develop rabies. These reports are based on cases without treatment. In our own studies we tested 28 strains of street viruses isolated from rabid dog brains, and although all the strains produced rabies in guinea pigs and mice by intracerebral injection only 5 were infectious by the intramuscular route. In our experimental methods of infection, which involved exposure of cutaneous, subcutaneous and muscular tissues to these 5 strains of street viruses the infectivity was quite irregular. It varied from 5 to 50 per cent in mice and from 1 to 80 per cent in guinea pigs. On the other hand, the S-1 fixed rabies virus consistently infected about 70 per cent of the guinea pigs following use of the same methods of inoculation. From the information available in the literature and from our own results it appears that the infectivity of a rabies virus by the intramuscular route of inoculation depends more on the strain of virus than on whether it is a street or a fixed virus.

We realize that the methods of inoculation we used did not altogether simulate the natural inoculation occurring from a bite of a rabid animal. We believe however, that our methods did in many respects simulate the natural mode of infection. The wounds were produced in skin and muscle tissue, and in relation to the size of the animals they were deep, extensive and ragged. The virus was deposited in the wound and then worked into the muscle tissues with the tip of a blunt

hypodermic needle as it might be by the teeth of a rabid animal in the course of biting.

The mortality rates in experiment 16, in which we attempted to locate and expose with an incision the virus that had been injected into the muscle tissues of guinea pigs were considerably higher than the rates in our other experiments. No doubt it would be difficult by such a procedure to reach all of the virus so that effective treatment could be applied. This would explain some of the difficulties involved in local treatment of deep and punctured wounds. It also emphasizes the necessity of using antirabic vaccination in addition to local treatment.

The application of fuming nitric acid to the wounds of the guinea pigs caused severe chemical burns and scarring in about 90 per cent. The wounds healed slowly, requiring about four weeks for complete healing. On the other hand, the wounds of the guinea pigs that were treated with soap solution, tincture of iodine or sulfanilamide healed in about two weeks without showing toxic effects or excessive scarring. Less than 1 per cent of the guinea pigs in these experiments contracted intercurrent infections.

The results of these experiments show that cauterization with fuming nitric acid of wounds after experimental contamination with rabies virus is of definite value in preventing rabies. They also show that irrigation with soap solution is of equal or perhaps slightly more value. When either agent was applied within two hours after the inoculation of the virus only about one third as many guinea pigs developed rabies as among the untreated controls (tables 1 and 2). Treatment with fuming nitric acid or soap solution was only about two thirds as effective when applied in six hours as it was when employed after the thirty minute and two hour interval respectively.

As shown in experiments 17 and 18, sulfanilamide apparently did not aid in preventing rabies, neither did it appear to predispose to infection.

SUMMARY AND CONCLUSION

In experiments in which treatment of wounds contaminated with rabies virus was instituted within thirty minutes, only 11 per cent of those treated with fuming nitric acid and only 6 per cent of those treated with soap solution became infected, compared with about 63 per cent of the untreated controls. The application of treatment in two hours was apparently somewhat less effective, and its application in six hours was definitely less effective than when it was applied in thirty minutes.

In tests using a limited number of guinea pigs, the results of applying tincture of iodine within thirty minutes compared favorably with the results obtained following treatment with either fuming nitric acid or soap solution. However, when tincture of iodine was used after an interval of two hours it appeared to be considerably less effective than the other substances.

Packing the wounds with sulfanilamide after they had been treated with soap solution seemed to have no effect on the incidence of rabies.

The results of these experiments show that in the treatment of guinea pig wounds that have been inoculated with fixed rabies virus irrigation with 20 per cent solution of soft soap is just as effective as chemical cauterization with fuming nitric acid and possibly even more effective.

THE PREVENTION OF EAR AND NASAL SINUS COMPLICATIONS OF THE COMMON COLD

DAVID A. DOLOWITZ, MD
WALTER E. LOCH, MD
HENRY L. HAINES, MD
ARTHUR I. WARD, JR., MD
AND
KENNETH L. PICKRELL, MD
BALTIMORE

Practically all infections of the ears and nasal sinuses are secondary to acute coryza or nasopharyngitis and are due to bacterial invasions. The primary inciting agent may be a virus but prolongation of symptoms and complications are caused by pyogenic organisms. Nasal and throat cultures of large numbers of patients with acute coryza show that the predominating type of organism varies from year to year. A group of nurses at the Johns Hopkins Hospital during the winter of 1943 were shown by cultures to have pneumococci in the nasopharynx and pharynx three times as frequently as beta hemolytic streptococci, while during the winter of 1942 beta hemolytic streptococci had been the commoner type. In other years *Hemophilus influenzae* predominated.

Beta hemolytic streptococci, pneumococci and *H. influenzae* are the types of bacteria most commonly found in the nose and throat during acute coryza but as mentioned their incidence varies from year to year. In 1942 beta streptococci were found in 36.2 per cent of the patients examined, while in 1943 they were present in only 11.2 per cent, *H. influenzae* was found in 29.3 per cent in 1942 and in 12.1 per cent in 1943. The incidence of pneumococci was more nearly the same—25.8 per cent in 1942 and 34.6 per cent in 1943. These figures are based on the number of cases in which these organisms predominated in several cultures. A few colonies of beta hemolytic streptococci, pneumococci and *H. influenzae* may be found in cultures of an individual with no clinical evidence of infection.

Alpha streptococci, several types of gamma streptococci, *Neisseria catarrhalis*, diphtheroids and *Staphylococcus albus* and *Staphylococcus aureus* are found so frequently in the nose and throat of normal healthy persons that they must be regarded as the normal flora of the throat, but one or more of these types, particularly staphylococci and alpha streptococci, are not infrequently found in almost pure culture in an infected ear or sinus. The designation "normal throat flora" implies that the types of organisms mentioned are present in the cultures without predominance of any one type. It is worthy of note that in 1943 the nose and throat cultures of 11.2 per cent of the nurses with signs and symptoms of acute pharyngitis or coryza were reported as showing normal throat flora, while not a single report of this kind was made during 1942. This suggests that both acute coryza and acute pharyngitis may sometimes be due to a virus or some agent other than bacteria. So-called virus pneumonia was more prevalent in this hospital during the winter of 1943 than in 1942, but only 2 of the 12 nurses with an acute infection of the upper respiratory tract and normal throat flora had virus or atypical pneumonia.

The incidence of nose and throat complications of coryza is steadily decreasing among the general population, owing to the widespread practice of the family physician and the pediatrician of giving sulfonamides by mouth for every acute infection of the respiratory tract. However, one of the objections to giving large doses of these drugs by mouth and thus saturating the entire body to prevent or to cure an infection in one small area is that approximately 30 per cent of the patients develop nausea, dizziness, fever, cutaneous rash or some more serious evidence of sensitivity to the drug.¹ The ideal procedure would be to use bactericidal and bacteriostatic agents locally in minor infections and reserve administration by mouth and by vein for the more serious spreading infections. Powdered sulfonamides have proved very satisfactory for local application in wounds but are not suitable for insufflation in the nose and throat during acute coryza. Drugs used in the nose should be neither too alkaline nor too acid and must in no way interfere with the movements of the cilia.

Pickrell^{1a} in 1941 showed that a large burned area on the skin could be kept far more sterile by frequently spraying it with 2.5 per cent sulfadiazine in ethanolamine solution than by giving sulfadiazine tablets by mouth. The sprayed material is absorbed, and the concentration of sulfadiazine in the tissues in a localized area may be six times that in the blood stream. Thus the growth of organisms in the sprayed area is inhibited and further spread of the infection is prevented. This observation is the basis for spraying the nose and throat during the early stages of acute coryza. If the treatment is begun soon after the symptoms of infection appear and is repeated at frequent intervals, the concentration of sulfadiazine in the mucous membranes and lymphoid tissue soon reaches a level that inhibits growth of the bacteria in the region and prevents extension of the infection to the ears and sinuses.

AN INVESTIGATION OF THE METHOD

Infections of the sinuses and ears commonly follow acute coryza, and physicians are greatly in need of some simple, safe method to prevent them. A controlled study was made during the winters of 1942 and 1943 to test the value of the sulfadiazine spray when used not to prevent the common cold itself but to prevent the complications. Observations were made on 103 nurses at the training school in the Johns Hopkins Hospital. Nurses were selected because their living conditions, food and working hours were uniform and because they were available at any hour during the day for observation and treatment. A special nurse was employed to carry out the treatment as directed, since it was evident that no conclusions could be reached unless the number and the frequency of treatments and the amount of sulfadiazine solution actually sprayed into the nose and throat at each treatment were known. As a rule the nose and throat were sprayed from eight to twelve times a day for the first three days and from five to eight times daily for an additional three days. Unless the cough was unusually troublesome the treatment was omitted during the night. Irritation of the skin around the external nares was prevented by frequent application of cold cream or petrolatum. Nurses were asked to report as soon as possible after the first symptoms

From the Department of Otolaryngology, the Johns Hopkins University and Hospital.
This study was supported by a grant from the Lederle Laboratories, Inc. The sprays were donated by the DeVilbiss Company.

¹ This percentage is approximately correct for sulfadiazine, sulfathiazole and sulfapyridine but several recent reports indicate that 8 per cent have toxic reactions following oral or intravenous administration of sulfadiazine.
^{1a} Pickrell, Kenneth L. A New Treatment for Ear, Nose and Throat Infections. *Johns Hopkins Hosp.* 69: 217-220 (Aug.) 1941.

of an infection of the nose or throat because it is during this phase of infection that the best results are obtained.

The routine described previously² was followed in all cases. Without their knowledge nurses reporting with colds were alternately placed in a treated and a control group. In the treated group the pharynx and both sides of the nose were sprayed with 2.5 per cent sulfadiazine in ethanolamines solution, in the control group the solvent alone was sprayed an equal number of times. In all other respects the treatment was the same for the two groups. When patients in the control group had sinusitis, otitis, severe cough or sore throat they were at once transferred to the treated group.

Cultures were made of material from the nose, the nasopharynx and the pharynx of all patients at the first examination and daily thereafter until they were discharged—a total of fifteen to twenty-five cultures for every patient. The sulfadiazine spray usually cleared up the symptoms of an infection with beta hemolytic streptococci within twenty-four hours, and occasionally these organisms completely disappeared from the cul-

Incidence of Complications

Group Treated with Sulfadiazine Spray 5% in Ethanolamines (59 Patients)	Control Group Treated with the Solvent (Ethanolamine 8%) (44 Patients)	Group Not Participating in This Experiment Who Reported to Infirmary with Complications of a Cold (18 Patients)
Sinusitis 9.7% All cleared up with no local treatment other than sulfadiazine spray	70% Patients were transferred to treated group and in all sinusitis cleared up with no local treatment other than sulfadiazine spray	4.4% required hospitalization
Otitis 1.8% Cleared up with no local treatment other than sulfadiazine spray	4.5% Patients transferred to treated group and in all otitis cleared up with no local treatment other than sulfadiazine spray	8.3% required hospitalization tympanic membrane ruptured in 1 paracentesis done in 1
Laryngitis No laryngitis developed in any patient during treatment	2.3% Patients transferred to treated group	5.4% required hospitalization
Sore throat No sore throat developed in any patient during treatment	10% Patients transferred to treated group	12% required hospitalization
Cough 8% Cough developed during treatment	44% developed cough	Incidence not known

tures after the first day of treatment. Pneumococci and staphylococci were more resistant, but evidently the drug reduces the virulence of these organisms since the incidence of complications was much less in the treated than in the control group. Proper use of the sulfadiazine spray prevents many of the complications of the common cold. The truth of this statement is attested by the contrast between the incidence of sinusitis, otitis, laryngitis, sore throat and severe cough in the treated group, the control group and an additional group of 183 nurses who did not volunteer to take part in this study but reported at the infirmary with colds.

The incidence of sinusitis in the control group may seem high, but acute coryza is an infection of mucous membrane, and the mucous membrane of the nasal cavity is continuous with that lining the sinuses. The sinuses are infected with every cold, but symptoms of sinusitis appear only when the cilia cease to function or when a thick discharge or edema interferes with drainage. In most of the cases in which a diagnosis of sinusitis was made it was based on the findings in the antrums. When both antrums transilluminated

clearly and no pus was seen under the anterior ends of the middle turbinates at the first examination but became apparent in subsequent examinations the diagnosis was sinusitis even though the patient had no pain or fever. Every patient was examined daily with the transilluminator, the nasal speculum and the nasopharyngoscope during the period of observation. The incidence of the more severe type of sinusitis in the infirmary group (4.9 per cent) indicates that many of the 30 per cent in the control group would have recovered spontaneously even if they had not been transferred to the treated group and had not received the sulfadiazine spray. It seems equally evident, however, that in some a severe sinusitis was prevented by the use of the sulfadiazine spray.

Summary—A controlled bacteriologic and clinical study was made to determine the effectiveness of 2.5 per cent sulfadiazine solution in ethanolamines (Pickrell's solution) used as a spray for the nose and throat, in preventing complications of the common cold. Cultures of material from the nose, the nasopharynx and the pharynx and a complete examination of the upper air passages were made before treatment was begun and daily thereafter until the patient was discharged. Without their knowledge the nurses were alternately placed in a treated and a control group. In the first group the nose and the pharynx were sprayed with the sulfadiazine solution from eight to twelve times a day for three days and from five to eight times a day for two or three additional days, in the second group the corresponding areas were sprayed an equal number of times with the solvent alone. In all other respects the treatment was the same in the two groups. The primary object of this treatment is not to cure the common cold, which is probably initiated by a virus infection, but to prevent the bacterial infections of the sinuses, the ears and the pharynx that so commonly follow it.

COMMENT

There can be no doubt that bacterial infection is the important factor in the prolongation of symptoms, the loss of time from work and the more serious complications of the common cold.

Bacteriologic studies show that the sulfadiazine spray does not sterilize the nose and throat with the occasional exception of a beta hemolytic streptococcus infection. Some strains of this organism are so sensitive to sulfadiazine administered in this way that many patients with a red, edematous pharynx and constitutional symptoms due to streptococcal infection are cured within twenty-four hours both bacteriologically and clinically by using only 20 to 25 cc of the 2.5 per cent sulfadiazine solution as a spray.³ To get this result the treatment must begin as soon as possible after the sore throat is noticed and while the bacteria are still on the surface of mucous membrane and lymphoid tissue and accessible to the action of the drug. The results are not so good if treatment is begun after the fourth day of the disease. Other strains of streptococci and pneumococci do not disappear or noticeably diminish in numbers in the cultures, but clinical results suggest that they lose their virulence or their ability to become virulent. Extension of infection to the sinuses, ears or larynx of properly treated patients is rare. Although *H. influenzae* is presumably not sensitive to the sulfonamides, certainly the incidence of complications due to this organism seems to be reduced.

2 Bordley, John E., Crowe, S. J., Dolowitz, David A. and Pickrell, Kenneth L.: The Local Use of the Sulfonamides, Gramicidin (Tyrothricin) and Penicillin in Otolaryngology. *Ann. Otol. Rhin. & Laryng.* 51: 936 (Dec.) 1942.

3 The blood level for Sulfadiazine was 1.6 mg per hundred cubic centimeter.

Some patients object to the taste. Others complain of irritation of the skin around the external nares, which can be prevented by frequent application of cold cream or petrolatum. About 3 per cent of our patients were sensitive to the sulfadiazine spray, as evidenced by sneezing and increased rhinitis. One patient developed a generalized cutaneous rash. Another patient had definite localized tissue sensitivity. A year previously her hand had been badly burned and was treated with sulfadiazine. This treatment produced a generalized cutaneous rash, which cleared up when the drug was withdrawn. The burn healed promptly and had been perfectly well for at least eleven months when she came to us with acute coryza. After three days of spraying her nose with the 2.5 per cent sulfadiazine solution the scar on her hand became extremely red and irritated. These symptoms gradually disappeared after the sulfadiazine spray was stopped. The only manifestation of sensitivity was in the scar on her hand.

The possibility exists that general sensitivity may develop in some patients, following local application of sulfonamides for a minor ailment, which might prevent administration of these drugs by mouth for a really serious illness at some future time. No evidence of this was observed, but the subject deserves the consideration and study of members of the medical profession.

SINUSITIS AND INFECTIONS SECONDARY TO THE COMMON COLD

TREATMENT WITH STABILIZED AQUEOUS SOLUTION OF SULFATHIAZOLE SODIUM WITH DESOXYEPHEDRINE HYDROCHLORIDE

FREDERICK MYLES TURNBULL, M.D.

LOS ANGELES

WILLIAM F. HAMILTON, Ph.D.

ELI SIMON, M.S.

AND

MELVIN F. GEORGE, JR., A.B.

BURBANK, CALIF.

Two years ago Turnbull¹ reported that a 5 per cent solution of the sodium salt of sulfathiazole brought greater relief from the symptoms of chronic sinusitis than any other preparation he had used. It relieved congestion, opened the nasal passages, promoted drainage and relieved pressure headaches. The use of sodium sulfathiazole appeared to be a perfectly safe procedure, and the results obtained in cases of sinusitis seemed to justify further investigation. The solution was reported unstable when exposed to light and air, as it tended to crystallize and discolor.

By adding sodium sulfite we were able to make the solution stable to light, air and heat. A vasoconstrictor was then added to the solution, decreasing congestion and thus assisting the antibacterial action of the sodium sulfathiazole. dl-Desoxyephedrine hydrochloride—discovered by Ogata in 1919 and, like the original sulfanilamide, a "sleeper" for twenty years—was found to be compatible with sodium sulfathiazole and actually to form a new sulfonamide drug, desoxyephedronium sulfathiazole.

Because of the presence of this new compound, the vasoconstrictive action of the solution was so pro-

nounced that a concentration of only one eighth of 1 per cent of dl-desoxyephedrine hydrochloride was necessary to obtain adequate shrinkage of the acutely congested membranes of the nose. Such activation is known as synergism, and this was demonstrated by clinical and laboratory work.

Synergism permitted the use of a very small proportion of the vasoconstrictor and therefore appeared to give the optimum clinical results—shrinkage of swollen tissues, drainage and ventilation of the sinuses without the after-effects so commonly experienced with prolonged use of vasoconstrictors, such as secondary congestion of the membrane, sneezing, sleeplessness, nervousness and tachycardia. Further, the incorporation of a vasoconstrictor enabled the sodium sulfathiazole to reach the deeper layers of the nasal mucous membrane.

Our results have shown that if the solution is used early in colds many were apparently aborted and also that the pressure pains in the acutely blocked sinuses were relieved. The stable, vasoconstrictive solution used in packs in the nose on acutely swollen membranes and left in place for twenty to thirty minutes effected noticeable relief, and patients reported improvement the day following treatment instead of the usual complaints after former methods of treatment with comments of "no relief" or "worse, with a sleepless night."

CLINICAL EXPERIENCE

In our experience of over 1,000 cases of nose, throat and ear infections, the following conditions have been treated:

Sinusitis, acute and chronic frontal, maxillary, ethmoid, sphenoid

Rhinitis, pharyngitis, laryngitis, tracheitis, acute and chronic

Otitis media suppurativa, acute and chronic

In acute sinusitis with headaches and in acute head colds it is well to saturate the packs with the solution and place as high in the nose as possible without discomfort. If the nose is very sensitive, a spray of 1 per cent solution of cocaine may be used first. The patient should be lying down (modified Proetz position), and at five minute intervals instillation of from 10 to 15 drops in each side of the nose should be continued until the swollen tissues are sufficiently shrunk to give relief from pressure. This usually takes twenty to thirty minutes in severe cases. In this way a very complete shrinkage of the congested mucous membrane results without blanching, sneezing or subsequent swelling.

For home treatment patients were instructed to use spray or drops with sufficient frequency to keep the nose open. At the beginning of the treatment this often necessitated using spray or drops at five minute intervals, usually two or three times until the deeper tissues in the nose were reached.

Chronic sinusitis was treated by irrigating the affected sinuses and following with the instillation of the solution into the sinuses together with the use of spray or drops at home.

Acute pharyngitis and laryngitis were treated by spraying the nose and throat and, in office treatment, the larynx and upper trachea.

Acute suppurative otitis media was treated by myringotomy and medicated tampons in office treatment, and by drops in the ear and nose and in the epipharynx by the patient at home.

From the Research Laboratory, Chemical Division, Lockheed Aircraft Corporation.
¹ Turnbull, F. M. Intranasal Therapy with Sodium Salt of Sulfathiazole in Chronic Sinusitis, J. A. M. A. 116: 1899-1900 (April 26) 1941.

Chronic suppurative ears were treated by cleaning thoroughly with peroxide, followed by insertion of tampons, home treatment consisted in the prescribed use of drops.

This type of treatment we have found safe and effective. In children the treatment has been especially effective, particularly when the nose was blocked from colds and acute or chronic sinusitis. Packs used in the swollen nose opened it up and gave relief without discomfort so that the child soon overcame fear of treatment.

For elderly people and in systemic involvements in which surgery is contraindicated, the therapy has offered a form of treatment that has produced considerable relief.

SAFETY AND EFFECTIVENESS IN SPECIAL CASES

Membranous Laryngitis of Alpha Streptococcus Origin—The patient's blood count showed leukocytes 3,300 following oral administration of six tablets of sulfadiazine over a period of twelve hours. Stable sulfathiazole solution was used as a spray in the nose, throat and larynx every hour. The following day the

Variation in pH

Compound	pH
1% neosynephirin (Stearns)	2.5-4
Isophren solution (Brommel)	2.5-4
1% propadrine (Sharpe & Doherty)	7.8-5
1% ephedrine solution (Lilly) (single sample)	7.9
Glucoc Fedrin (Parke Davis)	4.8-5.8
1 ephedrine compound (1% ephedrine sulfate) (Lilly) (single sample)	6.0
5% solution of mild protein silver (single sample)	8.9-9.1
Metaphedrin Aqueous Isotonic (Abbott) (single sample)	10.0
1% ephedrine compound in oil (Lilly) (single sample)	10.5
Values given are subject to change dependent on the age and condition of the preparations	
The pH of stabilized sodium sulfathiazole solution with dl-desoxyephedrine hydrochloride is 8.6-9	

leukocyte count had risen to 5,300 and the next day to 7,000 with clearing of the membrane in the larynx.

Acute Infectious Mononucleosis with Acute Alpha Streptococcus Membranous Tonsillitis—The patient was seen at the hospital on the twelfth day of the disease. The temperature was 104° F, leukocytes 14,800 polymorphonuclears 14 per cent, lymphocytes 83.5 per cent. Sulfathiazole orally with local use of stable sodium sulfathiazole solution brought the temperature to normal on the third day. A membrane which had covered the tonsil and part of the pharynx with dyspnea, disappeared.

Six unfavorable reactions have occurred in over 1,000 cases. In 4 the nasal congestion was not relieved or was made worse, in 1 a skin reaction resulted, around the nose, in 1 there was a rise in temperature. All these patients were allergic to the sulfonamides.

ALKALINITY

Comparative study of nose drop medications shows wide variations in pH as presented in the table.

It is indicated that a mildly alkaline sulfonamide solution is preferable for nasal medication because

1 The sulfonamides have the greatest bacterial action in the pH range of from 8 to 10 (Schmelkes and Wyss²)

2 Schmelkes Franz C and Wyss Orville. The Synergistic Action of Sulfonamides Wetting Agents and Azochloramid. J. Bact. 43: 1 (Jan) 1942

2 Ciliary motility shows greatest activity in the pH range of 8.2-8.6 and slows down in slightly acidic solutions, pH 6.5 or less (Negus,³ Gray,⁴ Schafer⁵). Use of stabilized aqueous sodium sulfathiazole with dl-desoxyephedrine hydrochloride has been shown to allow ciliary action to continue for a long period of time.⁶

3 Effective concentrations of the sulfonamides are readily obtainable in mildly alkaline solutions.

TOXICITY

Hummel⁷ states that in the mouse there are no permanent ill effects from the use of a 5 per cent solution of sodium sulfathiazole (not stabilized), there is a pronounced inflammatory reaction the first few days and after this the effect on the mucosa is almost nil.

The olfactory membrane, which is first affected when irritating drugs are used as Turnbull had previously found, is not injured.

The toxicity of desoxyephedronium sulfathiazole has been studied by Richards⁸ who reports that "toxicity of the compound is certainly not greater than that of desoxyephedrine itself."

BACTERIOSTATIC AND SELF-STERILIZING PROPERTIES

In a test for self-sterilizing properties of the stable sodium sulfathiazole solution it was found that "there is a gradual diminution of bacteria over a period of six hours, but about one sixth of the total number inoculated still remains viable at this time."

Stable sodium sulfathiazole solution was also submitted to a cooperating university laboratory to determine if the action of sodium sulfathiazole against *Staphylococcus aureus* was in any way altered by virtue of its chemical combination with dl-desoxyephedrine hydrochloride. It was found that "the average percentage inhibition of hemolytic *Staphylococcus aureus* in tryptone broth by sulfathiazole (125 mg per hundred cubic centimeters) was 73.0, and by sulfathiazole (125 mg per hundred cubic centimeters) when combined with dl-desoxyephedrine hydrochloride at pH 7.8 was 70.3."

CLINICAL OBSERVATIONS

In acute colds, stable sodium sulfathiazole solution combined with dl-desoxyephedrine hydrochloride treatment resulted in rather prompt relief and the duration of the infection was apparently shortened. This was also true in acute sinusitis with less tendency to become subacute or chronic.

In chronic sinusitis many cases reacted favorably where formerly surgery would have been indicated. There is no intention to suggest that this is a cure or that it substitutes for surgery when massive pathologic changes of the membrane or bone exist but indications are that it will greatly reduce the number of sinus surgical operations that might otherwise be necessary.

Acute suppurative otitis media has been a much less frequent complication. Chronic suppurative otitis media that has resisted other forms of treatment has cleared up without a radical mastoid operation.

CONTINUOUS CAUDAL ANALGESIA

AN ANALYSIS OF THE FIRST TEN THOUSAND
CONTINUOUS CAUDAL ANALGESIA
THE REPORT OF THE AUTHORS'
FIRST THOUSAND CASES

ROBERT A. HINGSON, M.D.
AND

WALDO B. EDWARDS, M.D.
Surgeons, United States Public Health Service
PHILADELPHIA

"The Poena Magna the chief or the great pain of the Romans which referred to the pangs of childbirth has been the object of attack by medicine men, midwives and physicians for centuries. The fear of it in the hearts of women has been a contributing factor to childless marriages and one of the major factors of the one-child family in our present civilization. The absolute alleviation of it in selected cases has been accomplished by continuous caudal analgesia.

"The failure of medicine men and midwives to deal with this pain adequately, if at all compelled women in labor to seek the services of physicians. The cries of women in pain, not usually fears concerning the welfare of unborn babies have brought physicians to the bedside. With physicians came poppy leaves and bitters, wine and morphine ether and chloroform, nitrous oxide and scopolamine, paraldehyde and the barbiturates, cyclopropane and ethylene, avertin and hypnosis. Yet women in travail still cried out through muffled anesthesia, screens of analgesia and curtains of amnesia as they were delivered of babies in varying degrees of narcosis and anoxemia."

Continuous caudal analgesia was designed to relieve the pains of labor and delivery. Properly administered, it furnishes a comfortable labor and delivery, and a vigorous, crying baby in the overwhelming majority of instances.

The history of the development of caudal and continuous caudal analgesia has been described in detail in numerous medical publications.²

Our purpose in this paper is to report the first 10,000 cases managed with continuous caudal analgesia in North American medical schools and teaching hospitals and to present the results of our first thousand cases so managed. It seems timely to discuss the modifications and improvements in the technic which have developed with increasing experience. It is also desired to discuss in detail the indications and contraindications based on the accumulated experience of many physicians. Finally, we desire to present frankly all the complications thus far encountered and the precautions necessary to avoid them.

The accompanying questionnaire was sent to obstetric clinics several months after we had presented teaching demonstrations in them. These reports indicated that 10,000 obstetric labors and deliveries were managed

with continuous caudal analgesia with the incidence of success indicated in the results of fifty-five clinics.

The percentage of success with this method seemed to vary directly with the experience of the operator and the percentage of complications and failures seemed to vary inversely with the experience of the operator.

In our series of 1,150 cases, 1050, or 91.3 per cent have been managed through labor and delivery without resorting to any other form of analgesia or anesthesia. The reasons for supplementary anesthesia have been

1 The inability to insert the needle in the canal, or faulty insertion recognized within one hour. Sixty-five cases, or 5.6 per cent.

2 Increased anxiety on the part of the patient with emotional distress, which indicated sedation and general anesthesia. Twenty-three cases, or 2 per cent.

3 The accidental escape of the needles in 5 cases, or 0.43 per cent. It was decided that reinsertion in these cases would increase the hazard of infection.

4 Cases of monsters or abnormal babies as previously determined by x-ray. Five cases, or 0.43 per cent.

5 Discontinuance of the procedure because of the reaction of the patient. One of these was a case with convulsions in which an overdosage of the drug had been given. The other was a case in which there was a manifest increase of nausea and vomiting. Two cases, or 0.17 per cent.

The other 1,050 cases were managed successfully through labor and delivery with continuous caudal analgesia. During this time the patients were usually kept on their sides. Occasionally, when the level of analgesia rose to a higher level on the dependent side, the patient was turned to the opposite side.

All the patients were offered every meal, and they were able generally to partake of fluids and nourishment before and after delivery.

Of the 1,050 patients whom we managed successfully with continuous caudal analgesia, 679 were primiparas and 371 multiparas. The average length of analgesia for primiparas was six and one-half hours and the average dosage of metycaine was 4.5 Gm. The average time of analgesia for multiparas was two hours and twenty minutes and the average dosage of metycaine was 2 Gm.

Since the introduction of continuous caudal analgesia with the malleable needle technic we have tried constantly to improve our apparatus and refine our technic in order to provide the maximum of safety to the patient, in addition to developing the facility of administration for the doctor. Some of the technical difficulties reported in the earlier part of our series were overcome with the perfection of our present instrument. While we have used this apparatus almost exclusively for all of our series, other physicians, in an attempt to prevent the recurrence of the early difficulties of needle breakage, have devised other forms of apparatus and modified technics.

Thus far from the literature there have been reported three important methods of administration of continuous caudal analgesia:

1 The malleable needle technic with the closed circuit apparatus.

2 The ureteral catheter technic with both closed and broken circuit apparatus.

3 The continuous drip caudal analgesia technic with the closed gravity apparatus.

The special malleable needle technic with the closed apparatus has been used by us in 1,000 of our cases. Of the 10,000 cases reported, this technic has been used in 6,400 cases. This is the technic of fractional dosage.

in which an initial dose of 30 cc of 1.5 per cent metycaine is used is soon as the labor has been definitely established to relieve subjective pain. Supplementary doses are injected at intervals varying from forty minutes to an hour and a half.

In our hands it has given increasing satisfaction with the minimum of complications. We have been able to teach this technique readily to others with greater facility than would be experienced in teaching the catheter and the continuous drip method.

Nevertheless each method has its own merits and demerits which should be thoroughly understood before its use is attempted.

In our preliminary studies we used the following cocaine derivatives and substitutes in varying concentrations and solutions of distilled water isotonic solution of sodium chloride isotonic solution of three chlorides (Ringer's solution) and isotonic Ringer-metycaine modified solution: (1) procaine hydrochloride (2) metycaine (3) pontocaine (4) nupercaine, (5) monocaine and (6) eucupin.

pressor substance as we did with procaine and pontocaine. When an obstetric patient is able to keep up her normal fluid intake during labor and when the level of analgesia is not permitted to rise above the umbilicus, less than 8 per cent of parturients will have a blood pressure drop of more than 20 mm of mercury and this drop is usually symptomless.

In cases of persistent vomiting in labor in which dehydration is also a problem any local anesthetic agent exerting a block of the white rami communicantes presents a hazard that must be overcome by judicious use of a vasopressor substance, intravenous fluids and oxygen when the patient has a high degree of anemia.

ANATOMIC AND PHYSIOLOGIC CONSIDERATIONS

In a comprehensive review of continuous caudal anesthesia for anesthetists we stated that:

The anatomic proximity of the sacral hiatus to the nerves of the pelvis, perineum and the lower extremities makes this method applicable to all types of obstetric and gynecologic procedures. The peridural space surrounding the dura mater

Results of Questionnaire

	North American Clinics		Authors' Series	
	Number	Per Cent	Number	Per Cent
A. Number of cases managed with continuous caudal analgesia	10,000		1,750	
B. Number of cases with complete relief of pain	8,160	81	970	80.0
C. Number of cases with partial relief of pain	1,900	12	190	12.2
D. Number of cases considered as failures	700	7	100	8.8
E. Complications to the mother				
1. Immediate reactions following injection	710	2.1	8	
2. Number of cases with fall in blood pressure exceeding 0 mm of mercury in systolic reading	670	8.7	46	4.0
3. Increased nausea sometimes associated with vomiting	670	6.9	56	4.8
4. Infection at site of injection				
(a) Simple cellulitis around site of injection	80	0.8	7	
(b) Severe cellulitis or peridural abscess	0	0.0	1	
5. Broken needles	20	0.3	9	
6. Post delivery headache	40	0.4	7	
7. Neurologic sequelae attributed to method	280	2.8	3	
(The 7 include urinary retention with need for catheterization more than once post partum, residual backache, hypesthesias)				
F. Complications to the fetus	70	0.7	3	
G. Maternal mortality attributed to continuous caudal analgesia	4	0.04	1	
H. Uncorrected fetal mortality	101	1.6	16	1.4
1. Fetal deaths presumed to be due to continuous caudal analgesia	2	0.02	1	
I. Average interval between induction of analgesia and delivery. There are many answers to this question varying from 34 to 8 hours				
J. Observations regarding blood loss. 60 of the 63 doctors reporting indicated that the blood loss was less with continuous caudal analgesia than with other methods				

We prefer a 1.5 per cent solution of metycaine in isotonic solution of sodium chloride or isotonic solution of three chlorides because of the (1) high analgesic efficiency of the drug, (2) the reduced number of reactions that could be ascribed to the drug and (3) the rapid elimination of the drug with a quick recovery of nerve impulses and physiologic control after delivery.

However, we have found that some analgesia could be obtained with all the drugs mentioned. Procaine, pontocaine and monocaine in many instances gave results closely approximating the relief we achieved with metycaine. Recently we have reviewed all our original comparative experiments with these various drugs after the report of Irving Lippincott and Meyer with an indicated preference for pontocaine and the report of Siever and Mousel with a preference for procaine.

We have found that the blood pressure falls have been in direct proportion with the anesthetic efficiency of the drug and are apparently due to the pharmacologic effect of producing splanchnic and lower extremity peripheral vasomotor block. We find no evidence to indicate that the blood pressure drop is associated with the toxic effect of the drug used. In the greater number of our continuous caudal injections with metycaine we did not use a prophylactic vaso-

as a sleeve from the foramen magnum to the hiatus sacralis comprises the area between the dura mater and the periosteum lining the spinal canal but usually at the second sacral segment communication between these two parts is interrupted by the closure of the dura mater around the nerve trunks. In dissection of cadavers we found that the dura sometimes encircles the spinal nerves of the cauda equina and the filum terminale, with its distal sac extending no farther down the vertebral column than the fifth lumbar segment. In approximately 0.5 of 1 per cent it extends all the way to the fourth or fifth sacral segment. In these instances spinal fluid can be obtained by inserting a short needle through the sacral hiatus. While this phenomenon has been observed by one of the authors in only 9 in 2,000 caudal injections the occurrence of anomalies and malformations of the vertebral and spinal canals should be kept in mind.

On the outer surface of the dura in the epidural space especially at the sides are extensive venous plexuses which may be penetrated with the caudal needle. The operator should attempt to direct his needle always in the midline and just under the bony roof of the sacral canal in order to minimize this hazard.

The sacral canal terminates below in the hiatus sacralis forming a triangular opening the sides of which are marked by bony ridges known as the sacral cornua. This opening varies in different individuals. It may be abnormally large owing to a deficiency in one or more of the vertebral arches or it may be reduced even to the extent of complete obliteration by ossification.

We have also noticed in dissecting these peridural spaces that a median fenestrated, fibrous raphe is not uncommonly produced by the continuation of the dura along minute nerve fibers extending upward between the spines and the periosteum of the vertebral arches.

Nerve Supply to the Uterus—The classic work of Head, Sherrington and Cleland established that the uterus derives its extrinsic nerve supply from three sources, that is, the motor fibers to the uterus are derived from the sympathetic nerves of the aortic plexus reinforced by fibers from solar, renal and genital ganglions, the sensory fibers are derived from sympathetic nerves and ganglions of the eleventh and twelfth dorsal spinal segments and the sensory and motor fibers to the cervix and also to the birth canal are found in the sympathetic and parasympathetic plexuses communicating with the second, third and fourth sacral nerves. The perineum receives its nerve supply from pudendal and perineal plexuses from the lower somatic sacral nerves. Thus a peridural injection through the sacral hiatus of 30 cc blocks all the sensory fibers to the uterus and birth canal, but the motor fibers sending impulses from higher levels are untouched. We have substantiated Cleland's thesis in our dissection of cadavers and in our clinical observations on more than 1,000 patients. A total of 30 cc of indigo carmine was injected into the sacral hiatus of 60 cadavers. Dissection of the peridural space in every case revealed that the dye disseminated at least as high as the eleventh and never higher than the sixth dorsal segment. Clinically it was found that when there is analgesia of the skin over the distribution of the ilioinguinal nerves (receiving components as high as the twelfth dorsal segment) and the eleventh thoracic nerves, on both sides, there is always complete subjective absence of labor pains. Usually the initial dose of 30 cc of 1.5 per cent metycaine produces this analgesia. Unless the anesthetic solution ascends this high in the peridural space, the parturient experiences discomfort.³

When the analgesic agent is permitted to ascend to the higher levels of the thoracic peridural space there is diminution in the force and frequency of the uterine contractions with a retardation of the progress of labor noted. This observation has recently been substantiated with both the Murphy and Fenning tocographic determinations.

MAILEABLE NEEDLE TECHNIC AS RECOMMENDED BY AUTHORS

1 The patient is placed in the modified left lateral Sims position. The sacral and coccygeal area is cleansed with ether and prepared with one of the antiseptic tinctures.

2 The tip of the coccyx is palpated with the middle finger of the left hand, and the thumb is used to find the U or V shaped notch indicating the sacral hiatus between the sacral cornua. This is usually about 1½ or 2 inches from the tip of the coccyx. In cases in which there was a failure of the inferior sacral arches to fuse into the bony roof of the sacrum, this hiatus may be 2½ to 4 inches from the inferior caudal tip. Experience with the standard single caudal injections is a desired prerequisite for the success in the use of the continuous method.

3 The middle finger of the left hand then changes place with the thumb and marks the spot for raising the initial skin wheal.

4 A special apparatus has been developed for this procedure. The analgesic agent recommended by us is 1.5 per cent metycaine in isotonic solution of sodium chloride. Two Gm of the drug diluted in approximately 125 cc of saline solution in the reservoir bottle will most nearly approach this concentration. With a few cubic centimeters of this solution, skin anesthesia

is obtained by raising a skin wheal with a 25 gage, and deeper infiltration to the sacrococcygeal ligament with a 2 inch 22 gage, needle.

5 The special malleable stainless steel 19 gage needle is then inserted in the midline in the direction of the hiatus at about a 45 degree angle with the skin.

6 As soon as the bevel of the needle pierces the sacrococcygeal ligament, its reinforced metal collar is depressed through an arc of 1 to 3 cm and the needle is thrust slowly and evenly in the midline for 1 to 2 inches within the sacral canal, where its bevel should be inferior to the lowest extent of the dural sac. This may be ascertained by measuring on the skin with the stilet the approximate extent of the needle. The point of the needle should always be below the level of the second sacral spine.

7 The small section of tubing with special adapter is then slipped over the collar of the needle. The Luer-Lok syringe is securely attached to the adapter. A careful aspiration is performed.

(a) Should clear spinal fluid be obtained, the needle has pierced the dura and lies within the subarachnoid space. In such event the needle should be immediately withdrawn and the case ruled unsuited for caudal analgesia for fear of producing a massive spinal injection of the analgesic drug. Anatomic anomalies with such low lying dura are rare. (In our experience this has happened only twice in more than one thousand injections.) A failure to recognize this situation would be extremely hazardous, if not fatal.

(b) The withdrawal of pure blood indicates that the needle has pierced a small blood vessel in the highly vascular peridural space. In this event the point of the needle should be moved until blood can no longer be obtained. Then the injection is continued cautiously.

8 The danger of intraspinal injection, with appearance of spinal fluid previously mentioned (see 7) can be minimized if a trial dose of 8 cc of the solution is injected and further action delayed for ten minutes to see that a low spinal anesthesia does not ensue. Without relief of pain or loss of motor power in the lower extremities in ten minutes after injection, one can safely assume that the subarachnoid space was not entered.

9 After these precautions have been carried out, the hose end of the special 4 foot rubber tubing is secured over the collar of the special caudal needle. The tubing should previously have been connected to the remainder of the apparatus, all air having been expelled by filling the entire system with metycaine solution.

10 With the palm of the left hand firmly pressed over the skin area against the dorsum of the sacrum, 30 cc of 1.5 per cent solution is slowly injected.

11 Five per cent sulfathiazole ointment is then generously spread around the collar of the needle.

Indications that the Solution Is Being Injected into the Peridural Space of the Sacral Canal—(a) The patients usually experience a sense of fullness progressing to an uncomfortable sensation in one or both legs as the solution circumscribes the perineural components of the sciatic nerves. This sensation can be minimized by slower injections.

(b) There will be a progressive analgesia in the areas supplied by the coccygeal, hemorrhoidal, perineal, pudendal, ilioinguinal and iliohypogastric nerve. Analgesia should be complete in twenty minutes.

(c) There is relief of abdominal uterine cramping within five to fifteen minutes after injection.

³ Hingson, R. A., and Edwards, W. B. Comprehensive Review of Continuous Caudal Analgesia for Anesthetists, *Anesthesiology* 4: 181 (March) 1943.

(d) Pronounced vasodilatation, cessation of sweating and increase in temperature of the skin of the feet will ensue within five to fifteen minutes after injection. This phenomenon is often noticed on one side several minutes before it occurs on the other.

Indications that the Solution Is Being Injected Outside the Sacral Canal—(a) Failure of the injection to relieve pain within thirty minutes. (b) The appearance of an 'injection tumor' superficial to the dorsum of the sacrum.

Supplementary Injections—12 The supplementary injection will depend on the rate of metabolism of the drug by the individual patient. In our experience 20 cc of additional solution injected every thirty to forty minutes is sufficient to keep the parturient comfortable for the entire course of labor. We have continued our supplementary injections for a maximum of thirty hours and for an average of seven hours.

We consider this method of analgesia to be a specialized procedure which requires special training in order to attain uniform satisfactory results.

INDICATIONS FOR THE USE OF CONTINUOUS CAUDAL ANALGESIA

There are certain obstetric conditions which indicate the use of continuous caudal analgesia for both the mother and the child.

Premature Babies—The use of any sedative, amnesic or anesthetic is contraindicated in the case of premature or small poorly developed babies. All these drugs have been shown to be transplacental and have been rightly accused of obtunding the vital mechanisms of the fetus during and for several hours after birth. The survival of these babies is difficult enough without the addition of narcotic, hypnotic and anesthetic influence to their undeveloped respiratory and cardiovascular mechanisms.

Thus far in our series we have managed the labors of 20 women with premature infants ranging in age of development from 26 to 36 calculated weeks and from 2 to 6 pounds (0.9 to 2.7 Kg) in weight. In only 1 of these cases was there a stillborn infant. The others breathed spontaneously after delivery. It was not unusual for these babies to cry before their shoulders were delivered during a vertex presentation, and four breech deliveries in this group were entirely satisfactory. The progress of these babies during their first postpartum days seemed to us more favorable than premature infants managed by us and in other clinics delivered through other managements.

There are certain physiologic reasons why the premature infants do so well under continuous caudal analgesia.

1 Labor is generally shorter and usually spontaneous.

2 The lower uterine segment, cervix and perineum and birth canal of the mother are completely relaxed, producing the minimum of trauma to the baby's head in passage through the birth canal.

3 Convulsive and voluntary expulsive muscular powers of the mother are not suddenly brought to bear on the contracting uterus, thus increasing the intrauterine pressure around the body or head of the baby.

4 The mothers during these labors, alert and usually cheerful, are not secreting various harmful endocrine products such as epinephrine during moments of pain, anxiety and fear.

5 The blood sugar level and fluid balance of the mothers approach normal since they are able to keep up their fluids and foods. Therefore the hazard of dehydration and hypoglycemia is not added to the dangers of prematurity.

6 The baby may be delivered deliberately with no sudden and traumatic manipulations by the obstetrician as he controls the passage of the baby at will.

7 The minimum of blood loss and systemic shock to the mother prepares the physiologic stage for the prompt formation of maternal milk, which is vital to the premature infant.

Heart Diseases—We were impressed early in our series with the well being of cardiac patients under continuous caudal analgesia.

Segmental analgesia produced with indicated caudal doses of 1.5 per cent meprocaine solution (courtesy of Pitkin's Conduction Anesthesia)

There are certain physiologic phenomena which add to the burden of a diseased heart during the process of natural labor: (1) the emotional strain of the patient, often associated with cries of pain, (2) fear of what the next few hours will bring forth, (3) tachycardia, (4) voluntary straining. All of these increase the demand on a diseased heart. In some cases an actual decompensation with permanent myocardial damage develops. The stress and strain of labor has been known to account for an anoxemia which would contraindicate a general anesthetic.

The patient under continuous caudal analgesia, however, is at ease and does not need her voluntary expulsive efforts. The rhythmic contractions of the uterus will expel the presenting part into the birth canal and will usually deliver it to the point of perineal bulging.

continuous caudal block produces an obliteration of the lumbosacral curves or the "strut" of pregnancy with undesirable rapidity, we insist that our patients lie on their sides and have insisted that they remain on one or the other side throughout labor. They may be turned on their backs and delivered in the usual manner.

Since we have adopted this regimen the incidence of backaches during labor has diminished. About 5 per cent of our patients complain of some backache and a few of these also have an associated pain in the neck incident to subsequent injections. These pains are transient and rapidly disappear as the analgesia becomes more intense.

slightest change in her pulse and blood pressure. Subsequently the needle was rotated and the continuous caudal analgesia was continued to a successful completion with the delivery of a vigorous baby which breathed spontaneously. The second patient had 3 Gm of 6 per cent metycaine in 50 cc of solution injected by mistake at a single dose. The patient developed disorientation, complete motor and sensory nerve block to the nipples and a severe convulsion which was controlled with an intravenous barbiturate. She remained in this state of complete analgesia below the nipples for a period of six hours. The baby was delivered with outlet forceps without pain to the mother, and the baby breathed

TABLE 2—Comparison of Analgesic Efficiency of Drugs Used

Name and Concentration of Drug	Effectiveness of Pain Relief	Effect on Blood Pressure	Duration of Analgesia with 30 Cc Solution	Disadvantages as Determined by Reactions and Complications
METYLCAINE 1.5 per cent in isotonic solution of sodium chloride or isotonic solution of three chlorides	Profound 100 per cent pain relief, rapid in onset with complete relief often in five minutes	Blood pressure fall exceeding 20 mm in 85 per cent of 10,000 cases, satisfactorily treated with epinephrine	30 minutes to 2 hours with average of 50 minutes	1 Slight increase in incidence of nausea 2 Increased bladder atony for 48 hours (reported to us, but observed by us in only 1 case)
<div><chem>CCCCCCCC(=O)OCCCN(CCCO)CC</chem> HCL</div>				
PROCAINE 1.5 and 2 per cent in isotonic solution of sodium chloride	Profound 90 to 100 per cent pain relief, occasional cases not relieved with procaine would respond to metycaine	Incidence of blood pressure fall approximately the same as with metycaine, usually prevented with addition of 1:200,000 epinephrine	30 minutes to 2 hours with average of 40 minutes	1 Slight increase in incidence of nausea 2 Increased mental excitement
<div><chem>NC1CCCCC1C(=O)OCCN(C)C</chem> HCL</div>				
POMOCAINE 0.25 per cent and 0.2 per cent with 1:2,000,000 epinephrine in isotonic solution of sodium chloride	Generally satisfactory, but patients still complained of slight discomfort, 80 to 90 per cent effective, slow in onset	Blood pressure fall when used with epinephrine not so constant as with metycaine	1 to 5 hours average 70 minutes	1 Incidence of nausea definitely increased 2 Postdelivery complaints as regards hypalgesia and hypesthesia more constant
<div><chem>CC(C)N(C)CCOC(=O)C1CCCCC1</chem> HCL</div>				
MONOCAINE 0.75 and 1 per cent in isotonic solution of sodium chloride	90 to 100 per cent effective	Blood pressure fall similar to metycaine when used without epinephrine and epinephrine	30 minutes to 1 hour and 30 minutes, average 40 minutes	1 Nausea increased

Dermatitis—Thus far we have had only 2 cases of dermatitis in our series which we have attributed to metycaine. These were typical erythema multiforme lesions which cleared up spontaneously in two days. The subjective symptoms of itching were treated with calamine lotion and 1 per cent phenol. In both instances the rash developed within twelve hours after delivery in patients who had been under continuous caudal analgesia for more than six hours.

Convulsions—In our series there have been only 2 instances of convulsions. One patient had had 3 cc injected unintentionally into the blood vessel. She complained of tasting the drug within ten seconds and had a mild clonic convulsion with complete disorientation within twenty seconds. This condition cleared up spontaneously within a minute and a half without the

spontaneously. Neurologic examinations of the mother at the end of seven days, two weeks and six weeks after delivery revealed no residual complications which could be attributed to the analgesic agent used.

Headache—The headaches which have occurred in our series have been transient in duration. All of them occurred in cases in which the solution was being injected more rapidly in an attempt to gain a higher level of analgesia. It was determined that these headaches could be diminished or completely arrested if subsequent injections were made more slowly.

Vomiting—Nausea and vomiting one or more times during the course of labor and delivery occurred in 20 per cent of our patients. Since many patients under all forms of sedation and without sedation in labor have a tendency to vomit with complete dilatation of the

cervix we do not believe that this 20 per cent incidence in our series could be ascribed entirely to the drug used.

A few of our patients complained of nausea with each uterine cramp before the induction of the analgesia. After the analgesia was instituted the nausea ceased and the patients were able to retain their fluids and some servings of nutritious meals.

Several other patients became nauseated and vomited as the analgesia was near the end of its effective nerve block period.

Therefore we have concluded that nausea and vomiting during labor and delivery are in some way associated with the intensity of the pain and distress which the patient experiences. It appears that the pylorus will not function during a painful labor.

The relief of pain and anxiety will often diminish the instances of nausea. However in 5 per cent of our cases there has been recurrent nausea and vomiting coincidental with subsequent injections of metycaine solution. These we ascribe to the toxic action of the drug on the maternal organism.

Jaundice—We have had no instances of jaundice in the mother at any time during the postpartum period even though some of our patients have had impaired liver function and some of them were known to be eclamptic.

Hypesthesia, Hysteria and Bizarre Reactions—The complaint of hypesthesia includes complaints of unpleasant subjective numbness, dizziness, tinnitus, spots before the eyes, increased nervous irritability and residual postdelivery disturbances in sensation over the extremities, perineum or abdomen.

We have had only 2 patients complain of a postpartum hypesthesia. One of these patients complained that the numbness extended over both arms, the trunk and both legs. After a careful checkup by our neurologist who found no objective evidence of this complaint the patient declared that she felt much better and that her sensation returned completely by the third week post partum. Another patient has complained of a hypesthesia of the vaginal vault and rectal area since delivery of a baby three months ago.

A 15 year old Negro developed total hysteria which extended from her soles to her scalp on both sides a few minutes after the initial injection. She remained in the vegetable state for a period of one hour. A few whiffs of ammonia brought her back to the state of reality a few minutes later. In this case we purposely let the metycaine wear off and let her have one hour of strong uterine pains. After this chastisement she requested more metycaine and from then on her analgesia worked perfectly.

Drop in Blood Pressure—Patients under continuous caudal analgesia not only have a block of the nerve pathways transmitting uterine pain from the eleventh and twelfth thoracic sympathetic segments but also have a block of the upper lumbar sympathetic ganglia which produces a vasomotor dilatation of the blood vessels of the pelvic viscera and the lower extremities. This produces an increase in the volume of the vascular bed in much the same manner as would be experienced from a bilateral lumbar sympathectomy. Therefore in the hypertensive patients a definite fall in blood pressure is usual. This sometimes exceeds 80 to 100 mm of mercury in both systolic and diastolic pressure. In individuals with normal blood pressure this fall is never so pronounced. In 80 per cent of our cases there was no blood pressure fall at all throughout either

the labor or the delivery. In 20 per cent in our personal series of 1150 cases and in 27 per cent of the reported series of 10000 cases there was a blood pressure drop greater than 20 mm of mercury.

Some of the physicians who have used this procedure have put a vasopressor substance in the solution. In some instances this has been 1/20,000 epinephrine and in other instances it has been 1/5,000 ephedrine sulfate or 25 mg of ephedrine to 125 cc of this solution. It has been our recent practice to use no vasopressor substance unless the blood pressure should fall below 90 mm of mercury systolic. In these instances it is our practice to use 25 mg of ephedrine at this time either intravenously or intramuscularly depending on the need of the patient. In such a case either 25 mg of ephedrine or 10 minims of 1/1,000 epinephrine should be added to each 125 cc of the metycaine solution subsequently used to maintain the analgesia.

We have seen blood pressure falls with all of the recognized cocaine derivatives and cocaine substitutes for this procedure. We believe that the blood pressure fall may be attributed to the pharmacologic action of the drug with its associated vasomotor dilatation of the blood vessels of the lower extremities and splanchnic reservoirs rather than any toxicologic effect.

Contraindications—1 Infection over the site of the area to be injected. (a) furunculosis (b) carbuncle or abscess over the area, (c) infected pilonidal cyst (d) pyoderma, (e) fungous or *Tinea versicolor* infection.

2 (a) Anatomic anomalies of the sacrum or bony obliteration of the sacral hiatus. (This is a very rare condition which occurs less than once in 200 cases.) This condition will be found more frequently in the early part of the obstetricians' series.

(b) A low lying dura mater in which spinal fluid may be aspirated through the caudal needle. This is an absolute contraindication. The case should be termed unsuited for caudal analgesia and should be managed in some other manner.

(c) Gross deformities of the spinal column such as Pott's disease, scoliosis or exaggerated lordosis.

(d) Patients with sacra having no bony dorsal arches.

3 Patients with a history of sensitivity to one of the cocaine derivatives or substitutes.

4 Patients with advanced anemia unless the procedure is to be supplemented with the periodic or continuous administration of a high concentration of oxygen. These persons should be given a transfusion of whole blood if the anemia has reached a critical stage.

5 The psychically unsuited. (a) patients with a history of hysteria or vasomotor instability, (b) epileptiform seizure, (c) central nervous system disease or (d) persons who have had meningitis or encephalitis.

6 Cases of placenta previa, unless cesarean section under this form of analgesia is contemplated immediately after its institution. The cervix and lower uterine segment in these cases will become very much softened thereby increasing the possibility of hemorrhage.

7 Cases of bony disproportion between the pelvis and the presenting part of the fetus unless cesarean section under this analgesia is anticipated.

8 Extremely obese persons in whom the sacral hiatus cannot be palpated. It should be emphasized

that blind prodding with a needle by the untrained physician will certainly result in disaster

Of one hundred physicians who were given intensive postgraduate instruction in the technic of continuous caudal analgesia, ten of them stuck the needle to the side of or below the coccyx and into the rectum or pararectal tissues. One of these physicians inserted the needle through both walls of the rectum, the vagina and one lip of the cervix. Fortunately, the fact that the needle was malleable caused it to deflect away from the parietal bone of the baby.

It has been reported to us that a fatal injection of metyname was performed with a stiff needle into the cranial vault of the baby.

It is unwise to attempt insertion of the needle more than three times in any case. Multiple punctures should not be made and if continuous caudal analgesia cannot be performed by an expert immediately with a minimum amount of physical and psychologic trauma to the patient, other forms of sedation should be used.

We are convinced that continuous caudal analgesia will give complete relief of pain to the parturient with absolute safety to her and her baby, provided the procedure is supervised by a specially trained person. We have found that the ideal person for this responsibility is an obstetrician who has been fundamentally trained in the specialized form of anesthesiology. We have also observed that in some instances the specially trained obstetrician's nurse is able to make some of the subsequent injections and to determine the progress of the parturient with absolute safety. However, the obstetrician in charge of the case should be in absolute control of the management of the procedure and should be available for consultation immediately if the patient should need him.

SUMMARY

From our experience and the accumulated experience of others we believe that the following postulates should be emphasized by all obstetricians who use this method:

1 The incidence of operative obstetrics is increased. No physician should use continuous caudal analgesia unless he is well trained in the use of forceps.

2 The incidence of posterior positions is increased to about 8 per cent because of the relaxation of the levator muscles with the resultant failure of a large number of the fetuses to rotate spontaneously.

3 The incidence of transverse arrest in the mid-pelvis is slightly increased because of the failure of the patient to use her auxiliary expulsive forces.

4 In the hands of the experienced, to offset the first three disadvantages, all types of operative obstetrics are facilitated because of the relaxation of the cervix, lower uterine segment and perineum. This relaxed state is not achieved by any other form of general anesthesia.

5 No oxytocic drug should be given until after the termination of the third stage of labor, because the uterus in every instance after continuous caudal analgesia contracts firmly with the delivery of the baby. Hemorrhage during the third stage is therefore definitely minimized. Gentle constant pressure on the fundus of the uterus as the placenta separates will usually expel it within two to five minutes after delivery. When oxytocic drugs are given immediately after the birth of the baby, the incidence of trapped placentas is increased.

6 Continuous caudal analgesia should be started only after labor is definitely established and the patient is in need of relief from pain.

(a) The head must be engaged (unless for cesarean section).

(b) The contractions should be occurring at five minute intervals or less.

(c) There should not be any disproportion between the presenting part and the pelvis.

(d) Progressive dilatation of the cervix 3 cm. or more should be in progress.

7 The babies born under continuous caudal analgesia are just as alert and wide awake at birth as those born to mothers who had no form of sedation or anesthesia. Many of them cry before their shoulders are born. Therefore every attempt should be made to shield the mouth and nose of these babies from aspirating fluid and mucus as their noses cross the perineum.

8 The incidence of fetal mortality and morbidity may be expected to decrease considerably, since there is apparently less birth shock to them by this than by any other method.

9 The entire course of labor is altered⁵ from the pictures described in textbooks under other forms of management. The first stage of labor is definitely shortened, the third stage is shortened and simplified. However, the terminal part of the second stage of labor is greatly prolonged unless outlet forceps are used on complete dilatation of the cervix and descent of the presenting part to the perineal floor.

10 An understanding of the anatomy of the peridural space, the sacrum and the surrounding structures is essential. A thorough knowledge of the neurology of the pelvic viscera is a prerequisite. A familiarity with the pharmacology of the cocaine derivatives and substitutes used in this method is necessary. The proper interpretation of the physiology of labor as altered by continuous caudal analgesia must be studied diligently.

11 For success with continuous caudal analgesia, knowledge of the related principles of the basic sciences must be combined with a high degree of obstetric competence and a skilful application of this new technic in anesthesiology.

Discovery of Radium—The discovery of radium was an indirect result of the discovery of roentgen rays. In the early roentgen ray tubes the impact of the cathode rays on the glass wall of the tube produced a green fluorescence. This phenomenon suggested that there might be some relationship between visible fluorescence and invisible roentgen radiation. Jules Henri Poincaré, a physicist at the University of Paris, was the first to suggest the desirability of testing ordinary fluorescent or phosphorescent substances to see if they emitted invisible rays similar to roentgen rays. His colleague Henri Becquerel undertook a systematic investigation of these substances. They were placed on a photographic plate, which was wrapped in black paper and put aside for some hours. His results were all negative until he tested several uranium salts in this manner. With all of them a distinct photographic effect was observed. On Feb. 24, 1896 Becquerel reported his discovery at the Academy of Sciences.—Haagensen, C. D., and Lloyd, Ward, in *E. B. A Hundred Years of Medicine*, New York: St. Louis House, Inc., 1943.

Clinical Notes, Suggestions and New Instruments

LABORATORY IDENTIFICATION OF SULFONAMIDE RESISTANT GNOCOCCIC INFECTIONS

WALTER T. GOODALL, AB, R. GORDON GOULD, PHD
LOUIS SCHWAB, AB, AND VIRGINIA G. WINTER, BS
BOSTON

Sulfonamide resistance is an important factor in the therapy of gonorrhea and constitutes a formidable barrier in the present campaign for the complete eradication of this disease. An analysis by Cox¹ of over 700 cases of gonorrheal arthritis in the male treated with sulfathiazole, sulfadiazine and sulfamerazine shows that 70 per cent of the cases are clinically and bacteriologically negative within five days and that the remaining 30 per cent show varying degrees of resistance. The principal manifestations of sulfonamide resistance are (1) persistence of symptoms and positive cultures for from several days to many months and (2) persistence of positive cultures in asymptomatic carriers. The latter group particularly constitute a serious public health menace.

Evidence has been reported showing that factors within the invading gonococcus determine sulfonamide resistance more than constitutional factors within the host provided drainage is adequate and that proper therapeutic measures have been taken. The Bangs,² Cohn Steer and Seijo³ and Lankford, Scott and Cooke⁴ have studied the growth of gonococcus strains in the presence of sulfonamides by various methods in the laboratory. All these investigators report that in general the strains from resistant cases of gonorrhea tolerate a much higher concentration of drug outside the body than strains from responsive cases.

The aim of the work reported here was primarily to confirm the correlation of clinical and in vitro response to sulfonamides by an independent method. Since the results in a series of 32 cases gave a complete correlation the method was then modified for the purpose of providing a simple and rapid laboratory test for the typing of cases of gonorrhea into sulfonamide responsive and sulfonamide resistant types. The test is simple enough to be carried out readily in any clinical laboratory; it can be completed in two to four days after the first examination of the patient and finally it makes possible the prediction of the results of therapy. Most of the 32 original cases and 26 additional cases were then studied by means of the simplified test and a high degree of correlation was obtained. The original method, which was developed by two of us (W. G. and L. S.) gave a quantitative index of the sulfonamide resistance of each strain. It will be described in detail elsewhere and the strains studied by this method are reported here merely as sulfonamide resistant, responsive or partially resistant.

METHOD

Pure cultures of gonococci are obtained in the usual way prior to therapy using either the starch casein hydrolysate-meat

infusion medium of Mueller and Hinton⁶ or chocolate agar. From this pure culture small inoculums are streaked on a control plate of the Mueller-Hinton medium and on a series of three plates of the same medium containing sulfathiazole concentrations of 0.10, 0.25 and 0.50 mg per hundred cubic centimeters of medium respectively.

The medium is prepared as described by Mueller and Hinton and 0.1 cc, 0.25 cc and 0.50 cc of a 0.1 per cent solution of sulfathiazole added to 100 cc portions of the medium just before autoclaving. This medium should not be autoclaved for more than ten minutes at 10 pounds. The sulfathiazole solution is prepared by suspending 1 Gm of sulfathiazole in 10 to 20 cc of water adding sodium hydroxide solution until a clear solution is obtained (4 to 5 cc of first normal) and then diluting to 100 cc. Best results are obtained with plates less than 2 to 3 weeks old.

It is important to use an approximately standard amount of inoculum on each plate. The main source of error is the use of too large an inoculum since this may protect susceptible strains against the action of the drug.

Fig. 1—Simplified test with pure cultures. A shows a resistant strain and B a responsive strain. C shows another resistant strain (upper half of each plate) and D a partially resistant strain (lower half of each plate).

The plates are then incubated at 36 to 37 C in a candle jar for eighteen to thirty-six hours and read as follows:

1. Equally or almost equally good growth on all the plates indicates a resistant strain.

2. Good growth on the control and no growth, or only traces of growth, on the sulfathiazole plates indicates a susceptible strain.

3. Good growth on the control and intermediate degrees of growth on the sulfathiazole plates, with considerably better growth on the 0.1 mg per hundred cubic centimeters plate than on the 0.50 mg per hundred cubic centimeters plate indicates a partially resistant strain.

It has been found advantageous to spray the plates with a solution of the 'oxidase reagent' (para-amino dimethyl aniline hydrochloride) to identify the colonies as *Neisseria*. Occasionally contaminants resistant to sulfathiazole and closely resembling gonococcus colonies in appearance have been encountered but they are readily distinguished from gonococci by the use of oxidase reagent.

Photographs of plates treated in this way are given in figure 1 and show typical examples of the three types of strains: *Neisseria* colonies appearing black.

Partially resistant strains have been found to constitute only a small fraction of the total and both the other types may be readily classified by the use of only one sulfathiazole plate. The 0.1 mg. per hundred cubic centimeters plate is preferable for selecting the most responsive strains and the 0.5 mg. per hundred cubic centimeters plate for the most resistant strain. A second drug plate is, however, useful in providing a check on the first.

Time Required—The isolation of a pure culture requires twenty-four to forty hours and the test another twenty-four to forty hours, making a total time of two to four days. Highly resistant strains can be easily classified after eighteen hours of incubation, but the longer period of incubation gives a more reliable differentiation of partially resistant and responsive strains.

However, preliminary results obtained by Cox indicate that in cases of untreated acute gonorrheal urethritis the test may be completed in less than twenty-four hours after the first examination of the patient by using urethral swabs or urine sediment directly for the test, thereby eliminating the preliminary isolation of a pure culture. Figure 2 shows typical results obtained by this modification. Spraying the plates with the oxidase reagent is particularly useful here because of the frequent occurrence of contaminants.

Fig. 2.—Direct streaking with urethral swabs (A, B and upper half of C) and with urine sediment (lower half of C). Strain A is responsive and strains B and C are resistant.

Until more cases have been studied by this new direct method it should be regarded as only presumptive evidence and the test repeated with a pure culture. It has been reported that certain species of bacteria can protect susceptible bacteria from the action of the drug in mixed culture.

RESULTS

The data obtained by both the original and the simplified methods are given in the accompanying table, together with the clinical data.

Of the total 58 patients 22, or 38 per cent, were found to have resistant strains by one or the other or both methods. All these patients were decidedly resistant clinically, failing to respond to treatment in less than two to four weeks. Thirty-three patients, or 57 per cent, gave responsive strains and all these patients showed negative smears, cultures and symptoms on the first examination after therapy was started, with negative follow-ups thereafter. This examination was usually made forty-eight hours after drug was started, but occasionally the patient delayed his second visit for from three to six days.

The remaining 3 cases, or 5 per cent, gave partially resistant strains in vitro. Clinically, 1 resembled the resistant type and 2 were definitely intermediate, requiring approximately one week for cure.

Two patients each had two infections as denoted by the superscript on the case numbers.

Cultures were obtained before sulfonamides were administered in the clinic in all cases but 4 from the sulfonamide-resistant group. In an additional 4 resistant cases and 1 responsive case sulfonamides were taken before culture in the clinic.

7 Zimmerman, A., and Pike, R. M. A Satellite Phenomenon in Mixed Cultures of Bacteria on Agar Containing Sulfonamide. J. Bact. 45: 522 (May) 1943.

Several incidental findings are worth noting.

1 In this series of cases no relationship was found between the speed of cure with sulfonamides and the time after onset of symptoms at which sulfonamide therapy was started. In other words, it appears that a responsive case will respond immediately at any stage of the disease, while a resistant case will run its course no matter how soon sulfonamide therapy is started. Case 15 is worthy of special mention in this connection. This was the only responsive case in which drug had previously been administered, 50 sulfonamide tablets, and these without success. On the twenty-second day of symptoms sulfadiazine was given and an immediate cure within twenty-four hours resulted. A culture taken just before drug was given showed a responsive in vitro picture by both methods.

2 The in vitro inhibitory powers of sulfathiazole, sulfadiazine and sulfamerazine appear to be similar, though, weight for weight sulfathiazole is several times as powerful as either of the other two.

The strain from case 54 was first reported to be responsive by the simplified test and the method failed in this case to predict the result of therapy correctly. However, later tests showed it to have definitely more resistance than any of the responsive strains studied and it is therefore classified as partially resistant. It is to be expected that a small percentage of cases will give strains with a small degree of sulfonamide resistance making the prognosis doubtful but in this series all the strains except the one discussed were either decidedly resistant or responsive.

COMMENT

This method is an entirely practical typing procedure for use in the clinical laboratory, since it involves only elementary bacteriologic technique. In the hands of the average well trained technician, practically all cases of male gonorrheal urethritis can be definitely classified as sulfonamide resistant or responsive in from two to four days. An absolute bacteriologic diagnosis, including fermentation reactions, usually cannot be made in less time than this.

Of greatest importance is the fact that routine use of this test may serve as a guide in the therapy of any given case in the clinic. If the strain is responsive in vitro and the patient appears cured after one course of sulfonamide therapy, there is less need of follow-ups and he can be discharged with considerable assurance of a complete cure.

If the strain is highly resistant the patient is almost certain to respond slowly if at all to sulfonamides, and other methods of therapy are indicated. When penicillin is available for the treatment of a limited number of cases of gonorrhea,⁸ this test would be useful in selecting the most sulfonamide resistant cases with a minimum loss of time.

The test is also of value in focusing attention on patients who become asymptomatic carriers. These patients, although only a small fraction of the total, are of importance not only because they are probably more apt to infect others than are patients who are frankly ill but also because they spread sulfonamide resistant strains of gonococci.

SUMMARY

1 A practical rapid laboratory method for the identification of sulfonamide resistant and sulfonamide responsive strains of gonococci has been developed.

2 Forty-four cases of male gonorrheal urethritis have been studied by this method and a high degree of correlation has been obtained between the clinical response to sulfonamides and the in vitro response of the strain to sulfonamides.

3 The advantages of the routine use of this method in the treatment of gonorrhea are that (a) it permits an accurate prognosis of the results of sulfonamide therapy, (b) prognosis of potentially successful use of sulfonamides safely permits fewer clinical check-ups and (c) prognosis of sulfonamide failure indicates the desirability of other forms of therapy.

BALANTIDIUM COLI

REPORT OF CASE WITH PROCTOSCOPIC STUDY

I A DeLANNEY, M D, AND EDGAR H BEAHM M A
OMAHA

Balantidium coli is an intestinal parasite of pigs and human beings, however, infections by this ciliate in man are comparatively rare, as is indicated by the cases reported.¹ The organisms have been found also in the intestinal tracts of orangutans and monkeys—Awakura² found a *balantidium* in wild rats in Moscow, Russia. It seems therefore reasonable to assume that this parasite is a potential hazard because of its universal distribution and its numerous hosts.

In spite of the fact that the possibility for infection is great, the opportunity for proctosigmoidoscopic study of cases is not frequent because they are not readily recognized. The following case was extremely interesting to us.

M H, a white man aged 33, a farmer, poorly developed, entered the Creighton Clinic on Jan 7, 1941 complaining of periodic attacks of diarrhea of seventeen years' duration. The

Fig 1—Low power view of *Balantidium coli* obtained by scraping the rectal mucosa of the patient. Intermixed with the organisms can be seen some of the granular and amorphous debris which was removed concomitantly.

onset occurred in 1924, while he was camping on the Iowa State Fair grounds. The stools were watery in character and contained blood and mucus. He was taken to the emergency hospital and treated for three or four days. He was dismissed when the bowel movements were again under control. He has had periods of abatement and of exacerbation since. His condition has always been worse during the winter months than during the summertime. In 1935 the patient suffered a particularly severe attack of dysentery, and a diagnosis of

Endameba histolytica infection was made. Emetine was prescribed, but he could not tolerate the drug so the medication was changed to acetarsone. His condition improved after the administration of this drug, and normal bowel habits were established for a brief interval. The dysenteric condition recurred but was again controlled by the administration of another course of acetarsone. Subsequent exacerbations were handled in this manner and the patient would remain symptom free for periods varying from three to four weeks.

At the time of his entrance to this clinic his complaints were frequency of bowel movements (three or four per day), soreness and cramping of the lower part of the abdomen. His diarrhea had no relation to meals or to different types of food. The physical examination revealed numerous caries in his teeth, the tongue was coated, the breath was fetid (of a peculiar odor which was noted to be similar to that coming from the bowel on sigmoidoscopic examination), the left arm and the right leg were spastic, speech was slurring. There was tenderness on deep palpation over the right lower quadrant of the abdomen.

Proctosigmoidoscopy revealed a diffuse inflammation of the rectal mucosa. In the upper third of the rectum were several irregularly shaped diphtheritic patches varying from 1.5 to 3 cm in length and 0.5 to 1.5 cm in width. There were also numerous small, round, white plaques, these had the appearance of bacterial colonies, as they are seen growing on an agar plate. The plaques were easily wiped off and exposed a raw, hyperemic area from which blood exuded. Scrapings from these areas when examined microscopically, on a warm stage, revealed the vegetative forms of *Balantidium coli*. Photomicrographs were prepared of the stained specimens (figs 1, 2 and 3).

A low residue, high vitamin, high calory diet was ordered and carbarsone was prescribed, one tablet (0.25 Gm) to be taken twice daily for ten days. When the patient was seen two weeks later he stated that he no longer had a diarrhea. Proctoscopy revealed only a slight hyperemia of the mucosa, the white patches had entirely disappeared. There remained

Fig 2—High power view of the same material as in figure 1, showing greater detail of the internal structure of *Balantidium coli*.

only light areas corresponding in size to the plaques and having the appearances of superficial scars. Fourteen days after the carbarsone was stopped the patient stated that he did not feel well and that he was again having frequent bowel movements. Proctoscopy showed a diffuse inflammation of the mucosa which was partially covered with a white foamy exudate. Smears taken at this time contained an abundance of very active balantidia. Another course of carbarsone was prescribed, the same results as those recorded were observed

Since oil of chenopodium has been used with good results by some authors,⁴ the following treatment was employed. The bowel was flushed with a weak solution of sodium bicarbonate and this was followed by 4 cc of oil of chenopodium in 30 cc. of olive oil. The solution was instilled in the rectum by means of a small catheter and was retained for two hours. This treatment was again repeated in three days. Examination of

Fig 3—Oil immersion view of *Balantidium coli* showing clear cytochrome micronucleus, food vacuoles and surrounding granular debris.

the patient seven and fourteen days later showed that there was no improvement, however, when the amount of oil of chenopodium was doubled the mucosa appeared normal after only one week had elapsed. The patient remained free from symptoms for one month, therefore he was instructed to return to the clinic in six or eight weeks for a check-up. When he returned he again was having frequent bowel movements.

Proctoscopy revealed the same picture that was seen at the time of his first visit to the clinic.

Diodoquin tablets (Searle) were prescribed, ten tablets of 0.25 Gm size daily for twenty days. When the patient returned at intervals of one, two, four six and eight weeks he stated that his bowel movements were regular and that the stools were well formed. He was instructed to return in six months for another examination, provided there was not a recurrence of symptoms at an earlier date. The rectal mucosa appeared normal and *Balantidium coli* could not be demonstrated when he was next examined. The patient is feeling well and has gained considerable weight.

Eighteen months have elapsed since the administration of the diodoquin and there has been no return of symptoms or other evidence of the disease. The arsenicals and oil of chenopodium were of little value in the treatment of this case.

Whooping Cough—Of all the infectious diseases of childhood that occur in epidemic form, perhaps none is more important from the point of view of both morbidity and mortality than is whooping cough. The disease occurs both endemically and in epidemics and is most serious when complicated by secondary pulmonary infections, these are produced as a rule by those organisms that commonly inhabit the upper respiratory tract. When uncomplicated by secondary infection whooping cough is rarely fatal, when death does occur it is more or less accidental and usually is due to suffocation accompanying convulsive seizures or to hemorrhage within the cranial cavity incident to the violent spasms of cough which characterize the disease.—Forbes Wiley D. *Reaction to Injury* Pediatric Williams and Wilkins Company, 1943

Special Article

AMERICAN HEALTH RESORTS

CLIMATE AND DISEASE

C. A. MILLS, MD
CINCINNATI

These special articles on spa therapy and American health resorts were prepared under the direction of the Committee on American Health Resorts. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the committee. These articles may be published later as a Handbook on Health Resorts.

Certain fundamental principles of climatic effects should be kept constantly in mind when spa therapy is being considered. In many types of disease the climatic background of a spa will exercise a considerable influence over its possible benefits to the patient. Facts showing just how and why this is true have not been sufficiently appreciated by the medical profession, hence this article, setting forth the pertinent information available.

Climate is now beginning to receive the attention its importance warrants. Through its dominance of ease of body heat loss it largely determines the energy level on which man may exist in a given region and we now know that much more than mere working ability is attached to this energy level of existence. All vital functions of the body are based on the energy derived from cellular combustion of foodstuffs, but as an energy conversion machine the body is not of high efficiency. It is thus very sensitive to the ease with which its waste heat can be thrown off, and it is here that climatic dominance is exercised. Where heat loss is accomplished easily, growth is most rapid, maturity comes early, resistance to infection is highest, energy for thought and action is most plentiful, and health assumes a positive and dynamic quality. As heat loss becomes more difficult, all these indexes of vitality are depressed and a lower, more vegetative level of existence results.

Physicians, particularly in the intense climatic contrasts of America, should have a clear understanding of these forces at work. Enlightened practice now goes far beyond the mere diagnosis and treatment of disease. Underlying most research into the treatment of disease has been the ideal of disease prevention—the maintenance of unhindered health. Among the factors influencing this maintenance of health, climatic environment probably will be found as important as adequate food supply or genetic background. Proper food is, of course, an essential requirement, but so too is the ability to utilize this food. With the lower combustion level of people in tropical warmth, more vitamins are needed to utilize each gram of food than are required for optimal response in cooler climates. Man is less energetic in warm climates but he is a more efficient working machine and shows less evidence of bodily and mental stress. In cooler regions where more dynamic and buoyant health prevails, the most acute and worrisome problems facing the medical profession arise from the wear and tear of too strenuous an existence.

While mean temperature level and ease of body heat loss thus dominate the energetics of life there is a second climatic factor which in some regions seriously disturbs the smooth flow of healthful functioning.

Storminess or atmospheric turbulence, with the accompanying sudden changes in temperature pressure and humidity is now recognized as a major disturbing factor in certain regions of the earth where cyclonic storms prevail. These sudden changes in the atmosphere seriously disrupt tissue functioning in ways as yet little understood and seem closely related to the initiation of many types of acute infectious attacks. Storm changes certainly constitute a major health factor in regions where they are frequent and abrupt, but much more evidence must be accumulated before the physiology of their effects can be clearly understood. Physicians should realize that individuals differ greatly in their sensitiveness to storm changes. Some people are utterly unfitted for existence in a stormy region and should be advised of the advantages of migration to a region of lesser turbulence.

This article is offered in the hope that it may help physicians to a clearer understanding of the workings of these climatic factors. Knowledge in this field still is in the stage of rapid expansion but sufficient information already is at hand to warrant positive advice along several lines. The newness of much of this knowledge necessitates for its clear understanding a rather comprehensive presentation of the physiologic principles involved.

PHYSIOLOGIC CONSIDERATIONS OF CLIMATIC EFFECTS

Human Energetics—The most fundamental effects of climate are exerted on the energetics of human existence so let us first consider the body as an energy conversion machine. At all times it lives and functions only by virtue of the cellular combustion of foodstuffs. Much of this combustion energy is wasted however, because of low working efficiency. Man himself has designed a machine of greater working efficiency than the human body. As high as 37 per cent efficiency has been reached in Diesel engines, while even gasoline motors reach the 20-25 per cent efficiency exhibited by man the horse and dogs. The human body however, is much more limited than are inanimate motors in the temperature range within which it can function well. Even a very few degrees of rise or fall from the normal level seriously interferes with efficient functioning.

To meet this handicap the body has developed an intricate mechanism for regulation of heat loss. Through the vasomotor control of blood supply to the skin the amount of heat reaching the body surface for dissipation can be altered with great rapidity. Normal loss from the deeper tissues by direct conduction is slow and is impeded by the insulating layers of fat encountered, but the blood with its high specific heat capacity and speedy circulation can carry internal heat to the body surface at a rapid rate. Blood flow through skin capillaries may be increased as much as thirtyfold within a few minutes when a sudden need arises. When this increased flow through the skin proves inadequate for quick elimination of the heat of combustion the sweat glands become active and make possible a still greater increase in rate of heat loss by water vaporization.

This intricate heat control mechanism functions quickly to meet sudden changes in heat production (as in bodily activity) or in the ease of heat loss (as with sudden external temperature changes). With more prolonged changes in the ease or difficulty of heat loss however, the body adapts by an increase or decrease in its own basic rate of tissue combustion. Thus external heat that lasts only a few days calls into play only

the vasomotor and sweating mechanisms, but if such heat persists for ten days to two weeks there occurs a definite suppression in tissue combustion rate. Therein lies the chief reason why severe summer heat waves may persist for weeks but cause prostration and death in the affected population only during the first ten days.

It is this combustion rate response to the more prolonged changes in external temperature level and ease of body heat loss which holds greatest significance for man. Any decrease in total tissue combustion, enforced by difficulty in heat loss necessarily means a curtailment of energy available for carrying out such vital functions as growth, work performance, tissue repair and the fight against infectious invasions. Such direct linking of these vital functions to tissue combustion rate and ease of body heat loss, although logical enough, has not received the appreciation its importance warrants. Indeed there has existed among medical men in America a disbelief that any such dependence really exists. This disbelief dates back to the publication of a paper by Benedict and Cathcart¹ in which they cite oxygen consumption data on 14 subjects in Boston and claim a lack of any seasonal influence. Even though their own data show a strong tendency for lowest oxygen consumption to occur in July or August, and this in Boston where summer heat is rarely severe, this article has been extensively quoted as indicating that tissue combustion rates are independent of external temperature levels.

This point is of such basic importance in any analysis of climatic effects that recently it was made the subject of a special article² in which the available evidence was presented and discussed. As set forth in that article the evidence points conclusively to a clear inverse relationship between tissue combustion rates and prevailing external temperature levels in both men and animals (within physiologic limits). Practically all investigators who have looked for this heat suppression of combustion rate have found it. Let us next see what it means in terms of growth and other vital functions.

Growth—All types of experimental animals suffer a growth retardation when heat loss becomes difficult. This happens even though all factors of existence other than ease of heat loss are kept constant. Animals at 91 F eat only about two thirds as much food as at 65 F. Herein lies the principal reason why domestic animals do so poorly in tropical warmth, giving lean, stringy meat of strong flavor. Coarseness of the tropical forage crops and leaching of soils under the heavy rainfall may be factors of considerable weight, but suppression of tissue combustion by difficulty in body heat loss is probably more important.

Children show this same retarded growth and inferior adult size under tropical heat conditions, while in the optimal coolness of middle temperate regions growth is most lusty and adult stature greatest. The close relation of such growth differences to oxygen utilization is emphasized by the pronounced differences in vital lung capacity exhibited by individuals from the two types of climate. Vital capacity in Filipino college students is only a little over half as great as that of students in the northern part of the United States.

Sexual Functions—Onset of sexual functions and degree of fertility are closely linked to ease of body

heat loss and tissue combustion level. Most rapid development and highest fertility occur at environmental temperatures around 65 F. As difficulty in heat loss comes on and growth rate slackens, we regularly see also a later onset of sexual cycles in young females both human and animal, and lowered fertility. Animals mate freely at 90 F, but conceptions are difficult to obtain and result in small litters of puny young while at 65 F almost every mating results in a large litter of lusty offspring. Microscopic changes in gonadal tissues indicate that this suppression of reproductive tissue is extensive and very real. Spermatogenic activity in the testes is almost obliterated within ten to fourteen days of application of tropical moist heat. After several weeks of adaptation some recovery of function occurs but to a much lower level of activity than is seen at lower temperature levels.

Man, living under natural climatic habitats, shows just as striking sexual variations at different levels of environmental temperature as do laboratory animals. Onset of the menses in girls occurs earliest in middle temperate latitudes and comes at a progressively later age as more and more severe tropical heat is encountered. At the present time here in North America the earliest menarche is found in the upper half of the Mississippi basin. Nowhere else on earth do children grow with such lusty vigor and enter such early adolescence. Development in the Gulf states is somewhat retarded by the long summer of tropical moist heat, but most severe suppression takes place in tropical lowlands, where depressive moist heat renders heat loss difficult at all times.

Medical literature and lay belief back through the centuries, at least to the time of Hippocrates, have held that the earliest onset of the menses occurred in the tropics. Even though all recorded statistics contradict this belief, it is encountered among people of all lands both lay and medical. Since we know it has been handed down through medical literature for two thousand years without factual support, we can well presume that it may have originated several thousand years earlier still. Only twenty thousand or so years ago present middle temperate regions had polar climates and optimal temperature conditions for man were to be found only in what are now tropical or subtropical lands. That such beliefs, perhaps once based on real facts, can be handed down through many thousands of years without further supporting factual background is well illustrated by the ancient astrological beliefs so widely held today even among intelligent people.

Wherever human populations are exposed to seasonal swings in mean monthly temperature, highest conception rates nearly always occur when the mean temperature level is near 65 F. As mean temperatures rise above 70 F or fall below 40 F fertility is reduced. With really severe moist warmth, as in Japan's monsoon summer heat or in the prolonged severe heat waves in the upper Mississippi valley in North America, conceptions may be reduced as much as 50 per cent. Nor is this reduction in conceptions merely a result of less frequent intercourse in hot weather, for there occurs no significant reduction in the frequenting of houses of prostitution. Apparently both men and animals continue the mating urge in hot weather but suffer a sharp drop in biologic fertility.

Malnutrition from any cause tends to retard development of the sexual functions. Difficulty in body heat loss is no more effective in this respect than is inadequacy of available food supply either in total amount

1 Benedict, F. G., and Cathcart, E. P. Muscular Work. A Metabolic Study with Special Reference to the Efficiency of the Human Body as a Machine, Pub 187, Carnegie Institution of Washington, 1913.
2 Mills, C. A. Climate and Metabolic Stress. Am J Hyg. Sect A 29: 147 (May) 1939.

or in composition of serious childhood illnesses. The menarche usually is delayed in girls who have been subjected to any of these depressive influences during their childhood years.

Resistance to Infection—Although such factors as malnutrition, vitamin deficiency and exhaustion usually have been thought important in determining the body's ability to fight infection, there has been little apparent inclination to consider tissue combustion level. Yet such a relationship would seem logical, since all vitality factors must have their functional basis in the energy liberated from such combustion. It is infectious disease which kills people living under depressing tropical warmth while the more energetic residents of middle temperate regions die mainly from the degenerative and breakdown ailments. In 1932 we showed that ability to survive tuberculous infection was decidedly higher in Cincinnati residents who were born in the North than in those born in the Gulf states. Dealing only with deaths of tuberculosis among the indigent population of Cincinnati it was shown that the survival time from first symptom to death was almost twice as long in patients born in the northern part of the United States or North Central Europe as in those born in the Gulf states of North America or in the Mediterranean countries of Europe. Ability to survive attacks of acute appendicitis also is considerably higher in the North than in the South.

Human disease statistics, however, are influenced by too many extraneous factors to be of any great value in determining climatic effects, unless they can be substantiated by studies on experimental animals under carefully controlled conditions. Human data may supply indications of existing differences or trends but conclusive proof in such a matter must come from laboratory studies. Fortunately such studies³ have now shown that ability to fight infection is definitely higher under conditions that facilitate body heat loss than it is where heat loss is difficult. With all other existence factors except ease of body heat loss held constant, practically all mice adapted to 90 F. will be dead after inoculation with a given dose of pneumococcus organisms before those adapted to 65 F. even begin to succumb. If one uses a less lethal organism, such as a hemolytic streptococcus, the minimum lethal dose for the 65 F. mice is found to be about four times as great as it is for those kept at 90 F. Antibody production after thyroid vaccine injection into rabbits is almost twice as great in animals kept at the lower temperature.

Locke⁴ has provided support also for the idea that the combustion level is an important factor in determining resistance to infection. He found that ability of animals to survive pneumococcus inoculation or of human beings to maintain freedom from respiratory infection was related directly to their rate of oxygen utilization. The matter needs more thorough study, but in the main it would seem that man's susceptibility to infection and his chances for survival are conditioned rather strongly by his ease of body heat loss and the resulting tissue combustion level allowed him. Temperate zone man does not, then, enjoy greatest freedom for respiratory disease during the summer months because of better tissue vitality as has been so commonly supposed. Actually the fatality rate per hundred cases of acute appendicitis is almost twice as high in summer heat as in winter cold and tuberculosis runs its

most rapid course when symptoms of disease activity first appear in summer heat. It now seems almost certain that the summer freedom from respiratory infection is attributable in very large part to the lessened storminess of that season and the greater freedom from body chilling.

Sensitivity to Heat—In addition to the profound effects on tissue combustion rate and body functions exerted by moderate difficulties in heat dissipation there are also more acute disturbances brought by excessively high environmental temperatures. Such disturbances are predominantly problems of middle temperate latitudes. This is true for two reasons, both of which are involved in an explanation of the physiology of these excessive heat effects.

The first reason is that man's own internal heat production is highest in temperate regions and his necessity for rapid heat dissipation greatest. Either animals or men adapted for weeks or months to cool surroundings develop a high combustion rate, and this proves embarrassing when sudden difficulty in heat loss is encountered. People residing in tropical moist heat have adapted themselves to a lower rate of heat production and acute heat effects there are seldom seen except in newcomers from cooler regions. Severe heat waves of summer come on middle temperate populations suddenly and sometimes kill thousands before their body heat production can be brought down within their capacity for dissipation under the difficult conditions suddenly prevailing. Particularly prone to this embarrassment from the sudden heat are the less resilient sclerotic patients and those of limited cardiac capacity. Increased peripheral circulation to facilitate the loss of internal heat throws a greater burden on the heart and hence the heat wave dangers for those with heart trouble.

Animal and human studies have shown that ten days to two weeks are required for any considerable subsidence of basic internal combustion in response to external heat. Population masses demonstrate this delay in adaptation by being able to stand considerably more severe heat in August than in June or early July. In fact, most heat stroke epidemics occur in early July rather than in the hotter weather of August. But if a severe July heat wave was to be inflicted on these same populations at the height of their winter activity, its effects would be truly devastating—perhaps as much as would a North Dakota winter suddenly inflicted on the people of Manila, Singapore or Calcutta. It is, then, the prevailing internal heat production rate of man that largely determines his sensitivity to acute heat effects when faced suddenly with severe external warmth.

The second factor responsible for the greater prevalence of acute heat effects in temperate latitudes is that most severe heat actually occurs there. Dry bulb temperatures of over 100 F. are rare in tropical regions except in desert areas while temperatures above this level are not unusual during severe summer heat waves as far north as the prairie provinces of Canada. Heat deaths and prostration occur mostly in urban and desert regions and for somewhat similar regions. With the dense vegetation of tropical lowlands and less so in rural temperate areas the physical surroundings of man have a high water content. Green foliage is largely water, and the high heat capacity of water enables it to absorb large amounts of radiant heat from the daytime sun with little rise in temperature. Baked earth, desert sands and urban building or paving materials have a very low specific heat and suffer a material rise of

3 Mills, C. A. *Climate in Health and Disease*. Oxford Medicine Series, vol. I, chapter XI, pp. 453-500 (1935).

4 Locke, Arthur. Lack of Fitness as the Predisposing Factor in Infections of the Type Encountered in Pneumonia and in the Common Cold. *J. Infect. Dis.* 60: 106 (Jan-Feb) 1937.

temperature under the radiant heat load from the sun. In desert regions this daytime heat is quickly radiated off into space soon after sundown, but in built-up urban areas it tends to be trapped within buildings and to cause progressively higher temperatures as the heat wave persists day after day. Building construction in tropical cities takes account of this danger and provides for ample air currents to carry away any such daytime heat that gains access, but in temperate zone cities winter cold prohibits this open type of construction, and the trapping of daytime radiant heat makes the heat problem for urban dwellers worse with each added day of a summer heat wave.

Lack of space prevents full consideration of the physiologic and therapeutic aspects of heat stroke, heat exhaustion and heat cramps. Those particularly interested can find the matter treated in detail elsewhere.⁵ One point of great importance is the protection against severe

studies, however, and those of others in this field were carried out at approximately optimal environmental temperatures for the animal subjects, so that there was no way of knowing whether this ratio might not vary as external temperatures were raised or lowered.

In more recent studies on this point it has, in fact, been found that the optimal requirement for dietary thiamine is twice as high at 91 F. as it is at 65 F. Animals show definite inadequacy in the heat at dietary thiamine levels twice as high as those at which inadequacy appears in a cool environment.

With animals on vitamin free synthetic diets to which have been added the known B vitamins in pure form those kept at 65 F. seem not to miss the unknown B fractions ordinarily supplied to them as liver extract. Addition to their diet of liver extract or the newer B fractions (inositol, para-aminobenzoic acid, choline, biotin) seems to make little difference in growth rate or

Fig. 1—Climatic stimulation over the earth

heat afforded by a high intake of the B vitamins. Thiamine 10 mg. a day has been found much more effective than salt tablets in warding off the effects of severe heat, but it is probably safer to increase the intake of all the B fractions.

Vitamin Requirements—Since human vitality and energy level seem so dependent on ease of body heat loss and tissue combustion rate, it is well to look into the combustion process itself. Perhaps tissue requirements for the combustion catalysts are higher when the combustion rate is slowed down by difficulty in heat loss. With the lowered food intake of hot climates or in summer heat it may well be that a higher dietary content of thiamine and other combustion catalysts of the vitamin B group is needed to maintain optimal concentration for proper tissue oxidative processes. It has quite generally been considered, largely as a result of Cowgill's studies, that thiamine requirement is determined by the amount of dextrose there is to be burned, that a more or less constant ratio exists between thiamine requirement and total nonfat calories of the diet. His

development. In the heat, however, these newer and unknown fractions have now been found badly needed.

As pointed out recently,⁶ man relies on meats and other animal products for the greater part of his B vitamin supply. Nuts are also a rich source but are eaten in much lesser quantities, while the vitamin in legumes is largely destroyed by cooking processes. Of the vitamin rich cereals the only two in common use (rice and wheat) are robbed of their supply by milling methods. Meats thus assume a very important dietary role quite aside from their protein content. It is unfortunate that tropically grown meats and eggs have been found deficient in these essential vitamin catalysts.⁷ Residents of warm climates thus face a double handicap: they need a higher B vitamin intake but instead find their native animal products deficient in these elements. Hence they are depressed both by their difficulty in heat loss and by a widespread vitamin deficiency. In cooler climates the meats are richer in vitamin and the human need is less for each pound of food.

6. Waisman, Harry A. and Elvehjem, C. A. *The Vitamin Content of Meat*. Minneapolis: Burgess Publishing Company, 1941.
7. Mill, C. A. *The Influence of Climate on the Vitamin Content of Meat*. Bull. New York Acad. Med. 17: 922-933 (Dec.) 1941.

Man's higher requirement for the vitamin B fractions in tropical warmth, coupled with a poorer dietary supply, probably plays an important part in the widespread occurrence there of such deficiency states as beriberi and pellagra. The subject needs a thorough investigation, for on this situation may hinge a considerable part of the malnutrition and low physical level seen among tropical populations. The magnitude of the problem can be appreciated only when it is remembered that half the earth's human population lives under just such depressive heat as is being discussed here. We can as yet only guess at the many bearings this variation in vitamin requirement at different temperature levels may have in the problems of human welfare. Since it directly affects cellular combustion and the source of energy for all body functions it must of necessity have important bearings on all the vital processes and functions of the body. A whole new field seems to be opened up by this dynamic view of physiologic response to climate.

CLIMATE AND DISEASE

The preceding discussion of climatic physiology provides a most useful background for an understanding of the geography of many diseases. Tropical people, with their more sluggish combustion rate and lowered vitality, die largely from infectious diseases, energetic residents of cooler lands die from the breakdown and degenerative diseases. Only with pneumococcal and streptococcal infections, mainly respiratory or of the nasopharynx, is the attack frequency higher in temperate regions and then only during the seasons of great cyclonic storminess. Since these disease differences are based largely on demonstrable differences in physiologic response to living environment and are susceptible of a considerable degree of control, it seems wise that the medical profession consider them against their proper physiologic background.

It is not at all surprising that clearest climatic relationships should be found for the diseases of metabolic overstimulation or breakdown. Metabolic stress rises highest in middle temperate regions where most nearly optimal heat loss conditions prevail, while toward tropical warmth evidences of such stress progressively decrease. Diabetes, with its breakdown in ability to prepare dextrose for the cellular combustion on which all bodily energy depends, shows this climatic relationship perhaps most clearly, but the relationship is also quite evident for pernicious anemia with its exhaustion in the production of red cells to carry the oxygen from

lungs to tissues. Toxic goiter and hyperthyroidism seem involved in this same environmental influence.

Perhaps most worrisome to the medical profession of stimulating regions are the growing evidences of stress and failure in the vascular system. On this system falls the most direct load as tissue combustion increases, for it must transport to the tissues all the needed combustion factors. The advance of sudden heart failure toward ever earlier ages in American men of middle temperate latitudes is presenting an acute health problem. Over two thirds of American physicians dying in 1939 did so from primary failure of one sort or another in the circulatory system. Addison's disease with its adrenal failure and other exhaustion states such as myasthenia gravis and neurocirculatory asthenia also most frequently occur in middle temperature latitudes. And for some reason it is in these latitudes that can-

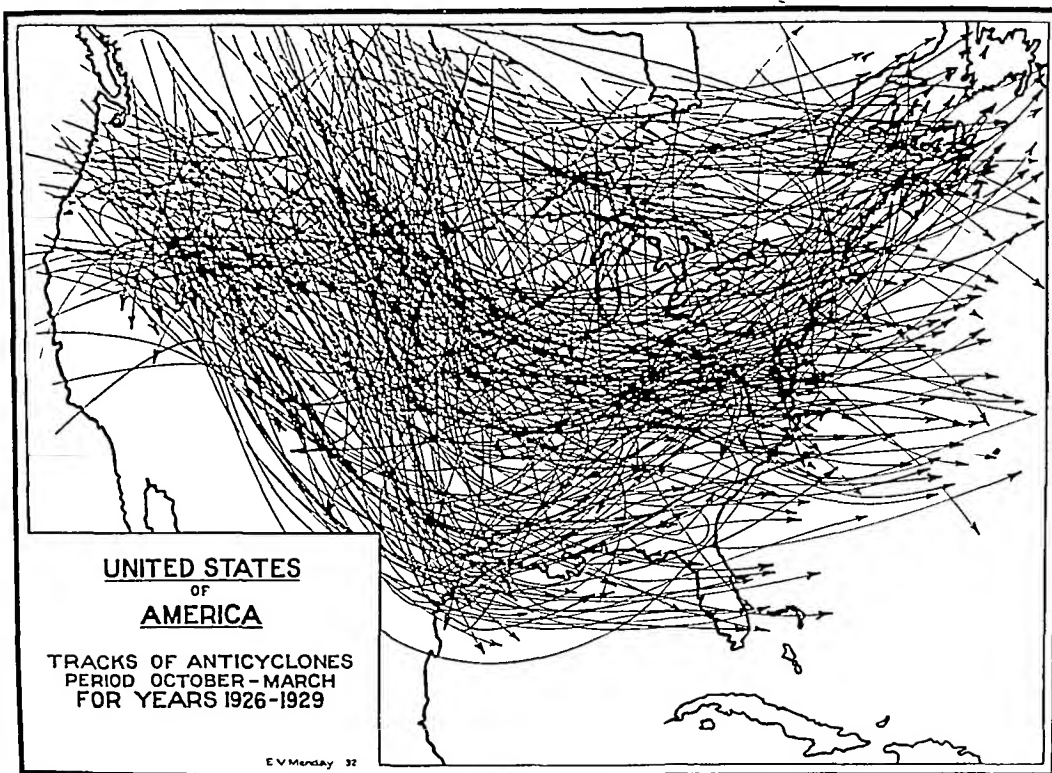

Fig. 2—Storm tracks over the United States winter highs 1926-1929

cer is presenting its greatest menace to man. Leukemia, which some consider a form of neoplasia, is almost exclusively a cool climate disease.

Infectious diseases present the other side of the picture, for with them greatest frequency and highest death rates go hand in hand with lowered tissue resistance in the debilitating warmth of tropical and subtropical regions. Temperatures there are more nearly optimal for parasitic and bacterial contamination of water and food supply, it is true, and added to this is the tremendous problem of insect vectors, but working beneath these major health threats in the tropics is the lowered general tissue vitality from sluggish cellular combustion. Figure 1, showing regional differences in the intensity of climatic stimulation over the earth, is presented here so that the reader may have before him this rough idea of the metabolic driving force exerted on man in the different regions. The methods used in calculating the indexes of climatic stimulation have been described in detail elsewhere.

Cyclonic storminess, with the atmospheric changes which accompany passage of successive "highs" and "lows" over a given region seems in some manner related to the initiation of infectious disease attacks. Respiratory and rheumatic infections are most closely involved in this type of climatic effect, but it also influences such other infectious attacks as acute appendicitis and puerperal septicemia.

Respiratory infections are associated with winter cold and storminess in north temperate latitudes to a striking degree. Life hazards of all sorts reach a peak at this season, for to the infectious dangers of the more violent storminess is added the greater stress of an increased metabolic load. In the southern hemisphere winter brings much less of an increase in life's hazards for there storminess is least during midwinter cold. The increase in mortality from respiratory infections in the

seaboard of North America and to a lesser degree the southwestern coastal region of Mexico. Low pressure storm centers passing over these regions seem to bring much the same respiratory disease problems as are faced by people living in the temperate zone storm belts. They do not have the body chilling from sudden temperature change, such as afflicts people of stormy temperate regions, but the pressure changes alone seem capable of initiating the infectious attacks. Careful physiologic studies are badly needed in this field of pressure change effects, particularly as regards disturbances in tissue water balance. Present knowledge is extremely sketchy and inadequate.

In order to give a general appreciation of the storm problem over North America, there is shown in figures 2 and 3 the course followed by anticyclonic high pressure centers affecting the United States during the

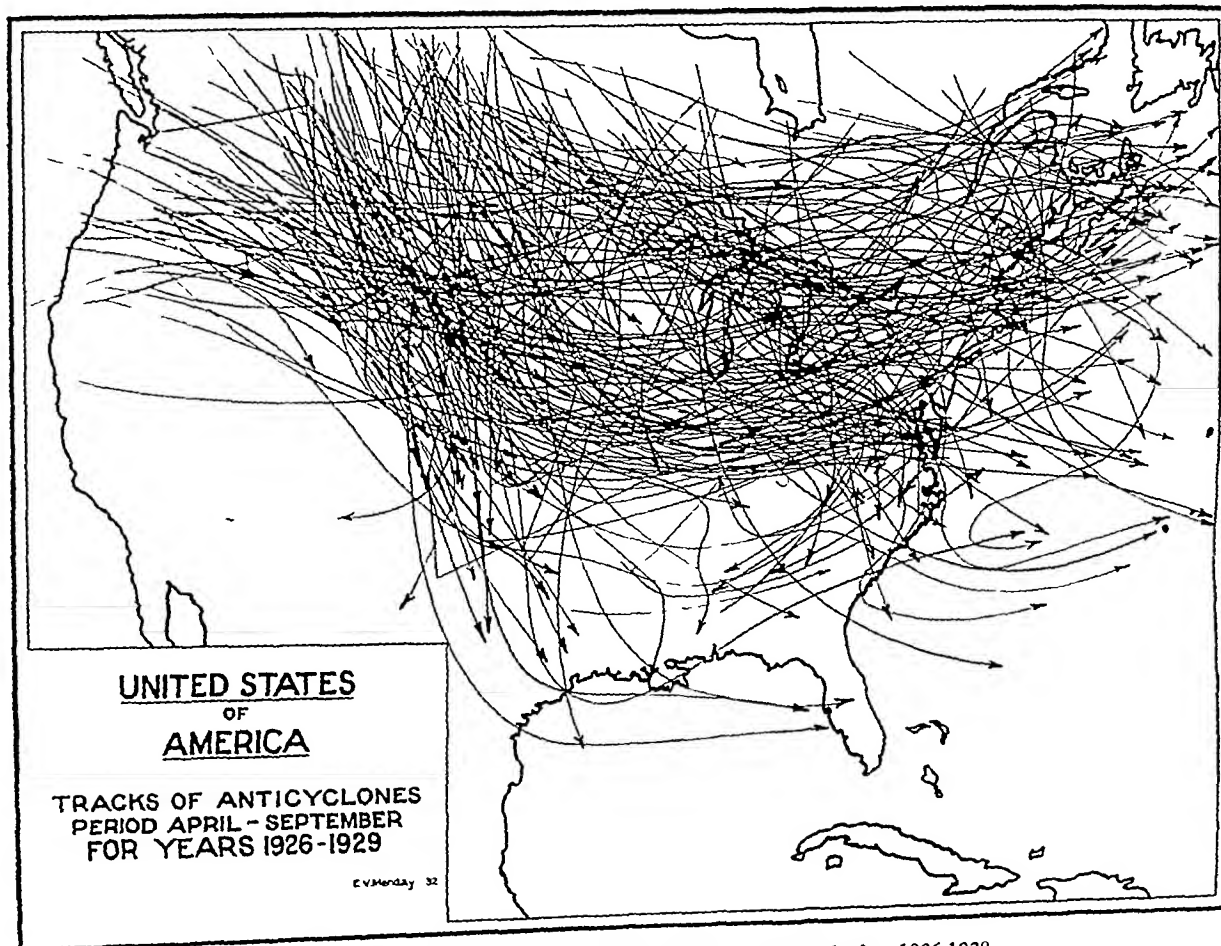

Fig. 3.—Storm tracks over the United States summer highs 1926-1929

United States from summer low to midwinter high is almost three times as great as it is in similar latitudes of Australia. And in the United States unusually stormy winters are accompanied by much greater frequency of respiratory illness and death than are those of lesser atmospheric turbulence. Hospital admissions for acute rheumatic fever at Cincinnati show a similar parallelism with seasonal changes in storminess.

This relationship of storminess to infections is just as evident on a regional as on a seasonal basis. Acute respiratory infections and acute rheumatic fever are predominantly diseases of stormy regions being worst in the middle temperate belt of cyclonic storms and least troublesome in calm tropical warmth. Respiratory disease in the tropics becomes a real problem only in those regions afflicted with cyclonic storms of the typhoon or hurricane type. Such regions include most of the Philippine Islands and the eastern Asiatic coast up to Japan, those parts of India around the bay of Bengal, most of the West Indies and nearby eastern

part of the United States or the highland regions of Mexico. This nonstormy zone expands northeastward during summer warmth, and at this season people of the Old South are left with the stagnant moist heat typical of tropical regions.

These two storm maps deserve considerable study for from them can be obtained much of the storm health story. It is in the stormy winter season and in the stormy regions of the earth that respiratory and rheumatic infections most severely afflict mankind.

CONCLUSION

Plans for spa therapy should not be made without due consideration of possible climatic and weather effects in the region to be chosen. Spas of the non stormy Southwest are to be preferred for patients with respiratory or rheumatic complaints while victims of the metabolic or degenerative diseases will usually benefit more in the calming warmth of the Gulf coast. For low vitality patients of tropical or subtropical area

to a year period 1926-1929. Each such major 'high' center affects an area 1500 to 2000 miles in diameter as it sweeps across the continent. From these figures one may get some idea of the relative differences in storm effects man faces in different parts of the continent during the winter, and the total reduction in storminess which comes with summer warmth. In the summer, storm centers cross the continent less frequently, travel more slowly and are accompanied by less abrupt and less extensive atmospheric changes. At no time of the year do major storm centers cross the southwestern

a summer sojourn in northern coolness works wonders; however they should beware of the cold and storms of northern winters. Each patient constitutes a separate problem in his relation to climatic environment, hence final decision must be made by the physician in charge. In reaching that decision the physician should be guided by the general principles of climatic and weather effects here set forth.

The therapeutic duties of a physician can no longer be concerned simply with the specific treatment of the disease at hand. He should look further afield for the larger forces affecting his patient's welfare and future health. And among the outside forces bearing on these more general aspects of existence climatic and weather influences are of great importance. The most perfect diet cannot lend to physical vigor and high vitality unless the heat generated in its use can be readily dissipated from the body. The physician of the future will therefore need to develop more deeply his interest in and knowledge of, climatic and meteorologic influences affecting man throughout his existence in the different regions of the earth.

5046 Oberlin Boulevard

Council on Industrial Health

THE COUNCIL ON INDUSTRIAL HEALTH HAS APPROVED THIS ARTICLE AS THE SEVENTH IN A SERIES ON MEDICAL SERVICE IN INDUSTRY
C. M. PETERSON, M.D., Secretary

INDUSTRIAL PHYSICAL EXAMINATIONS

PURPOSE

The purpose of industrial health programs is to promote and maintain the physical and mental welfare of all industrial employees. Physical examinations in industry are a means to this end.

Specifically, the objectives of industrial physical examinations are:

- 1 To facilitate placement and advancement of workers in accordance with individual physical and mental fitness
- 2 To acquaint the examinee with his physical status and to assist him in improving and maintaining personal good health
- 3 To safeguard the health and safety of others
- 4 To discover and control the effects of unhealthful exposure
- 5 To promote cooperative support and understanding of industrial health practices by employer and employee alike

Unjust or questionable exclusion from work through improper application of the findings on physical examination in industry is against the public welfare and contrary to sound industrial health principles.

SCOPE

- Industrial physical examinations should include:
- 1 Past medical family and occupational history
 - 2 Physical findings
 - 3 Personality appraisal
 - 4 Laboratory data
 - 5 Summary and recommendations

GENERAL PROCEDURES

Since placement of the worker in suitable employment is an important objective of industrial physical examinations the examiner will obtain best results only when he is familiar with the industry he serves. Medical inspection of the plant or industrial premises at regular intervals is essential to an adequate physical examination program as well as in other aspects of industrial hygiene.

Physical examinations in industry are classified under two major headings:

- 1 Preplacement examinations of applicants for employment
- 2 Periodic reexaminations (regular or special)

In either case the examination should be complete.

The examination should be conducted by the physician himself except such routine procedure as can safely be assigned to

trained assistants. The examinee should remove all clothing in a private room. Special arrangements and a nurse in attendance are necessary in examining women employees.

EQUIPMENT

Physical examinations will be facilitated if the following equipment is available:

Examining table	Dynamometer
Stools, chairs and couch	Centrifuge
Mirror	Microscope
Screen	Stethoscope
Scale and measuring rod	Ophthalmoscope
Metal measuring tape	Blood vacuum tubes
Spotlight	Otoscope
Distant and near reading cards	Reflex hammer
Color sense testing cards	Rubber gloves and finger cots
Nose and throat mirror	Tuning forks
Transilluminator	Hemoglobin outfit
Blood pressure instrument	Urinalysis equipment
Insulin syringes (2 cc and 10 cc)	Garment racks
Thermometer	

RECORDS

Content—No single form has been devised to suit all requirements. The accompanying example is a composite of many used successfully in industry. Regardless of form the records should contain:

1 Identification data: name, address, date and place of birth, race, sex, marital status, clock or social security number, and in certain circumstances photograph and finger prints. Some industrial physicians include name and address of next of kin.

2 Past medical and occupational history. Although details may be elicited by assistants, the importance of significant past health experience should be evaluated by the physician himself.

3 Physical findings.

(a) Preplacement examination. The attached form is designed for preplacement physical examination. Clarity and uniformity of expression are desirable. Variation in procedure will depend on specific industrial exposures and special job requirements. Examinations for transfer to other work or on return to work after prolonged absences are essentially preplacement in character.

(b) Periodic examination. Reexamination should be conducted in the same detail as the original preplacement examination survey. The recommended form can be readily modified to allow for reexamination and to meet special requirements. General principles are fully described in "Periodic Health Examination—A Manual for Physicians, Chicago American Medical Association 1940. Repetition of physical examinations must be determined by the physician in charge, based on his original examination and the nature of the industrial environment.

4 Personality data. Observation of temperament, personality and significant nervous or mental manifestations should be a correlated part of a complete examination. The brief outline suggested in the form has been used in practice with good results. Comparative schooling refers to the level of education attained in comparison with other children in the family.

5 Laboratory data. Urinalysis, hemoglobin determination, blood test for syphilis, chest x-ray examination, differential blood smear and blood sedimentation rate are employed in industry in about that descending order of frequency.

6 Summary and recommendations.

Coding—Usage varies in coding or rating physical and mental status, but the common intent is to classify examinees in one of the following groups:

- A General approval for all work
- B Approval for placement under medical supervision
 - 1 With limited physical exertion
 - 2 In nonhazardous work
 - 3 With orthopedic defect
 - 4 With defective vision
 - 5 With defective hearing
 - 6 With neuromental handicap
- C General disapproval for any work

From the public and industrial health standpoint the only absolute bar to immediate employment in ordinary occupations

should be communicable disease, psychosis or serious disabling injury or disease. Other considerations related to employer liability, workmen's compensation, factory acts and health codes must be determined separately for each jurisdiction.

Preservation and Use—The examining physician may properly put information derived from records of industrial physical examination to the following uses:

- 1. All major findings should be discussed with the employee, with emphasis on the importance of obtaining immediate and adequate medical care.
- 2. A transcript may be supplied to the employee's personal physician or to other official community health agencies on consent of the employee.

- 3. The employer should be given information in accordance with the suggested code described in this report to facilitate placement or promotion. A special simple form can be devised for this purpose. The employer should especially be notified of any condition or disability thought to be caused by faulty work environment.
- 4. Governmental agencies such as courts, workmen's compensation commissions or health authorities should be supplied with information on legally enforceable official order. In all other respects the confidential character of physical examination records should be rigidly observed and access should be granted only on request or consent of the examinee preferably after preliminary discussion with the examining physician.

Suitable filing equipment and training of personnel should be maintained for the safe keeping of all medical records in the medical department.

PERSONNEL

Physical examination is an important service of an industrial medical department having regular medical staff supervision. Where considerable numbers of examinations occur, nurses, technicians and clerks are helpful in securing and recording data in routine procedure. They require training which should be accepted as a special responsibility of the medical director.

In small plants, employers customarily make arrangements with individual examiners. A modification of this practice is to secure the services of an examiner from a panel of physicians approved by the county medical society for services of this kind.

THE JOINT COMMITTEE ON INDUSTRIAL OPHTHALMOLOGY REPRESENTING THE SECTION ON OPHTHALMOLOGY OF THE AMERICAN MEDICAL ASSOCIATION AND THE AMERICAN ACADEMY OF OPHTHALMOLOGY AND OTOLARYNGOLOGY HAS SUBMITTED THE FOLLOWING REPORT TO THE COUNCIL ON INDUSTRIAL HEALTH FOR PUBLICATION.
C M PETERSON, M.D., Secretary

THE KEYSTONE TELEBINOCULAR IN INDUSTRY

The Joint Committee on Industrial Ophthalmology has participated in careful analysis of visual records made in industry employing the Keystone Telebinocular. These records have been correlated statistically with subsequent job performance, incidence of accidents and with conventional professional aptitude tests. Evidence at present permits the following appraisal of the industrial use of the Telebinocular.

- 1. The Telebinocular is a sturdy, well made instrument, originally designed as a hand stereoscope. In 1933 it was modified by attaching a special shaft and slide holder, mounted on a stand. The slides are modifications of the original Ready to Read Tests designed by E. A. Betts to measure the visual performance of school children.
- 2. The record forms designed to classify employees for jobs in accordance with visual ability are based on arbitrary standards not justified by actual experiment on thousands of industrial employees. A simplified form has been developed by a member of the Joint Committee which has proved to be more practical. The Keystone View Company is also working on a simplified record form.
- 3. The Telebinocular visual acuity tests at distance have, through the work of the Joint Committee, been correlated with Snellen equivalents.
- 4. The depth perception test, while not accurately graduated can be used to advantage in screening out examinees in the lowest quarter of performance who are under consideration for special or dangerous assignments.
- 5. The phoria tests will identify most examinees with muscle imbalance lying outside the general range of normality. These measurements cannot be expressed in prism diopter equivalents.
- 6. The telebinocular has no adequate near point test of acuity in its series. Because of the importance of near point acuity in many jobs, special provisions will need to be made.
- 7. The color vision test, while inadequate as a whole, is useful in identifying certain types of color deficiency.
- 8. Several of the tests show little or no relationship to success on the job or with standard clinical practice in ophthalmology and are likely to create an impression of significant visual deficiency. Actually, the tests detect what might better be called substandard visual function.

The Joint Committee believes that the Telebinocular, used wisely by a properly trained tester will uncover subnormal visual performance not detected by the common industrial practice of testing for central visual acuity alone. However, the tests employed for determining muscle balance, stereopsis and color sense have definite limitations. The existing standards for acceptance or rejection of examinees in industry or for the classification of employees are not accurate enough for dependable use. Instead, individual standards should be created in each industry based on available data and the practical experience of associated medical and ophthalmologic staffs.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION
OF THE FOLLOWING REPORT HOWARD A. CARTER, Secretary

SIMPLE METHODS FOR PERFORMING ARTIFICIAL RESPIRATION

RALPH M. WATERS, MD
MADISON, WIS.

Artificial means to replace the act of breathing need not be complicated or difficult.¹ Any intelligent person, even a child, may be taught to perform artificial respiration which is adequate and safe.

In his teaching at Padua four hundred years ago Vesalius² emphasized the importance of proper respect for the thoughts of the ancients—an excellent attitude of mind for modern people. He demonstrated the adequacy of simple intermittent inflation of the lungs with air as a substitute for normal breathing. Goodwyn³ was the first physician to apply the knowledge of the exchange of oxygen and carbon dioxide during respiration. He called attention to the advantage of adding oxygen to the atmosphere used during artificial respiration. In the intelligent employment of these two contributions is embraced the beginning and the end of "artificial respiration." There is no more to it than that. And yet in the century and a half since Goodwyn's book was published much paper has been used in describing how and with what mixtures of gases ventilation of the lungs ought to be accomplished.

Children are thought to like mechanical gadgets, nevertheless, how frequently do we find father playing with the electric train weeks after Junior has found other interests. Enthusiasm for the clever construction and intricacy of a mechanical respirator is more likely to determine its purchase and use, even by a physician, than is thoughtful reasoning or experiment as to its physiologic effects, its simplicity, reparability and all round availability. It is not my present purpose to discuss the relative merits of the numerous manual maneuvers suggested for the performance of artificial respiration, nor do I intend to compare the advantages of the many mechanical gadgets manufactured for the purpose. It is desired only to emphasize four facts: (1) that, as Vesalius demonstrated, gentle intermittent inflation of the lungs with air can serve as an adequate substitute for normal breathing, (2) that, if oxygen is available, it is desirable, as Goodwyn suggested, to add this gas to the atmosphere used, (3) that, regardless of the method employed atmosphere cannot enter and leave the lungs if the air passages are obstructed, and (4) that elaborate equipment is not essential. If these four points are properly appreciated, any one can perform artificial respiration. It ought to be begun as soon as natural breathing stops by whoever is present at the time. Blowing into the subject's nose or mouth is the method which is always available.

Manual maneuvers (Silvester, Schafer) can also be quickly applied. If apparatus is used, the simpler it is the better.

Anesthetists find it essential to be prepared to do artificial respiration at a second's notice. Overdose of an anesthetic or depressant drug, as well as various other accidents, sometimes stops normal breathing of the patient during an operation. The equipment described here is constituted of materials similar to those constantly used by many anesthetists to contain the anesthetic atmospheres breathed by their patients. They are therefore always in the hand of the anesthetist when an accident happens. In fact, when the anesthetist is alert, cessation of breathing is rarely dangerous. The method of artificial respiration described in the following paragraphs has been used to "breathe" efficiently for the patient over long periods of time. It is even employed during some surgical operations to hold in abeyance for hours the normal movements of the respiratory muscles when such movements may interfere with delicate surgical procedures. Such experience constitutes evidence that serious harm from such artificial respiration need not result. Simple apparatus, similar to that used by the anesthetists, costs little, is light and easily transported and can be employed by any intelligent person to perform artificial respiration. No elaborate and expensive machine will do a better job of artificial respiration.

EQUIPMENT AND PROCEDURE

Any manufacturer of anesthetic's equipment can furnish a face mask with a 5 or 6 liter

Fig 1—A mask (1) to cover the mouth and nose and a sturdy rubber bag (2) connected to an oxygen cylinder (3) constitutes adequate equipment. A properly shaped pharyngeal airway (4) of metal or hard rubber when placed over the tongue into the throat (5) sometimes helps to maintain a free passage to the windpipe.

breathing bag of strong rubber connected to a rubber tube several feet long. A yoke to fit a small oxygen cylinder and a wrench with which to open the cylinder complete the assembly (fig 1). The operator holds the mask tightly over the nose and mouth and fills the bag with oxygen (fig 2A). If oxygen is not available, the operator may hold the rubber tube in his mouth and keep the bag partly filled by blowing into it. Compression of the bag with the hand (fig 2B) forces atmosphere into the lungs (provided the mask is in approximately airtight contact with the face and the upper air passages are not obstructed). Release of pressure allows the atmosphere to return from the lungs. Such intermittent inflation of the lungs alternating with pauses to allow for deflation accomplishes adequate ventilation. The bag will need to be refilled frequently enough to replace the atmosphere which unavoidably leaks from under the mask during inflation. The frequency of inflation is relatively unimportant provided a pause after each

1 It is well recognized that the various manual maneuvers (Schafer, Silvester and their modifications) to accomplish artificial respiration are capable of accomplishing adequate ventilation of the lungs when the air passages are not obstructed. The impression is gaining prevalence that when apparatus is used it must be costly and elaborate. This paper emphasizes the long recognized fact that very simple mechanical devices are satisfactory. No originality is claimed for the method described nor is it claimed to accomplish more efficient or safer pulmonary ventilation than the manual maneuvers.

2 Vesalius Andreas. *De humani corporis fabrica*. Basel: J. Oporini, 1543.

3 Goodwyn Edmund. *The Connection of Life with Respiration*. London: J. Johnson, 1788.

compression of the bag is sufficient to allow the chest wall to sink back to its passive condition and the lungs to collapse partially and force the inflated atmosphere out.

Artificial respiration should resemble normal breathing. The operator ought to estimate how frequently and how vigorously this subject, save for the accident, would breathe for himself. Such activity should be imitated as exactly as possible both in depth and in rate. As pressure is made on the bag the thorax of the subject must be watched to see when it begins to expand. If beginning movement of the chest can be seen or felt, enough pressure has been exerted and the bag should be released. The operator must be sure that the outflow of atmosphere from the lungs is not impeded by the weight of the hand against the bag.

Free Exchange Essential—It for some reason passage to the windpipe is not open, atmosphere may fail to reach the lungs or it may be forced down the gullet

Fig 2—The bag is filled with oxygen (A) and squeezed by the hand (B) to force atmosphere through the upper air passages and windpipe into the lungs. As soon as movement of the chest is seen indicating that the lungs are filling, the operator's hand releases the bag completely to allow the lungs to empty. Normal rates of breathing are 12 to 20 per minute. Try to imitate nature in both rate and depth.

into the stomach. To assure a free passage to the trachea and avoid blowing up the stomach or forcing vomited fluids, food or other foreign substances into the windpipe, three procedures may be useful.

1 Empty the mouth, nose and throat of any liquid (water in drowning, vomitus) or solid substance (food, tobacco, chewing gum, loose teeth). This can be done with the fingers, with a cloth sponge or, better by gravity. Place the patient on his stomach, face down.

4 If the mask is held in really airtight contact with the face for several minutes, too much carbon dioxide—produced by the patient—may accumulate in the bag. Usually the necessary addition of oxygen or air to replace that which leaks between the mask and the skin of the face during the pressure of each inflation serves to remove carbon dioxide. Even if leakless contact is maintained, artificial respiration for less than five minutes will not permit a harmful accumulation of carbon dioxide. If long periods of artificial respiration are maintained with this equipment frequent emptying and refilling of the bag is necessary. This is particularly important if breathing has stopped as the result of poisoning with volatile or gaseous substances such as ether or carbon monoxide.

and head lowered if possible (fig 3). A child can be "stood on his head." Hospitals are equipped with devices for sucking material from the throat.

2 The relaxed and swollen tongue may fall backward to sit on the opening to the windpipe. In the face down position, gravity tends to keep the tongue away from the opening. In addition, the operator may pull the tongue forward. (a) By pushing the jaw

Fig 3—When intermittent inflation of the lungs is done with the subject's face down, the head low and a pad under the stomach, water and other fluids may drain from the lungs and throat.

forward with pressure behind the angles of the jaw. (b) By grasping the tongue with a cloth (fig 4). To hold the tongue forward while a mask covers the face, a large safety pin may be passed through the midline of the tongue, a half inch from the tip. Persons needing prolonged artificial respiration are unconscious and the slight injury to the tongue caused by the pin results in little soreness afterward. (c) By placing a rubber or metal artificial airway if available (5, fig 1).

3 To prevent inflation of the stomach, the hand or a moderate weight may be placed over the upper part of the abdomen if the victim lies on his back, or a soft roll of cloth may be under his stomach when his face is down (fig 3).

ALTERNATIVE PROCEDURE

Intermittent Direct Inflation of Lungs by the Operator—If the apparatus just described is not immediately available, valuable time must not be lost. Lives

Fig 4—With your handkerchief the tongue may be pulled forward before gently passing an artificial airway over it (see 5, fig 1).

are sacrificed by neglecting the first thirty seconds after breathing stops. Direct inflation of the lungs is always at hand (fig 5). Either the nose or the mouth may be blown into while one hand of the rescuer holds the other portal closed. The other hand, resting on the subject's chest, perceives the point at which the chest moves. In other words, when the lungs are sufficiently inflated. If no movement takes place, obstruction is present and the air passages must be cleared by the various maneuvers described.

COMMENT

Natural breathing is a very delicately adjusted mechanism for causing the atmosphere to enter and leave the lungs. The frequency of exchange and the depth of each breath are attuned to the needs of the blood and tissues for oxygen. The amount of air which enters and leaves the lungs each minute therefore varies widely for each individual and for the same individual at different times. Artificial respiration will therefore rarely exactly simulate normal breathing. The life processes of the individual who has ceased to breathe are at a low ebb and hence his demand for oxygen is comparatively little. When the air passages to the lungs are not obstructed, efforts at artificial breathing are apt to be overdone rather than underdone. If obstruction is present the opposite is true. Thoughtful and deliberate attention to the movements of the chest resulting from one's efforts will succeed while hasty and thoughtless activity may fail. Remember the object of normal breathing—to ventilate the lungs with air or oxygen which flows gently and slowly back and forth through the windpipe to and from the air sacs. Try to imitate normal breathing for each particular subject.

Fig. 5—With his left hand the operator holds the subject's nose closed while he blows into the mouth intermittently. A handkerchief or other light material prevents contamination. The operator's right hand rests lightly on the chest in order that he may appreciate when air is entering the lungs.

SUMMARY

If a reasonably robust person ceases to breathe, adequate artificial respiration may sustain life until breathing is reestablished. Only disappointment can result from performing artificial respiration on persons who cease to breathe as a terminal event in the course of disease. Methods are most useful which are instantly available and simple.

1 When breathing has stopped, do not concern yourself with calling for help, moving the patient, wrapping him in blankets or any maneuver other than keeping up intermittent rhythmic exchange of the atmosphere in his lungs.

2 Utilize inflation of the victim's lungs from the lungs of the operator, or exchange by manual maneuver, if apparatus is not at hand.

3 If and when a mask, rubber bag and a cylinder of compressed oxygen are available fill the bag with oxygen and inflate the lungs by pressing on the bag.

4 In either case (2 or 3) use only sufficient pressure to expand the chest slightly. If one can see or feel the chest begin to expand as one blows or presses on the

bag enough pressure is being used. The amount of pressure necessary may be great if the air passages are partially obstructed. Try to relieve such obstruction as soon as possible.

5 Allow adequate time for the lungs to empty before inflating them again.

6 Persist until the subject breathes for himself or until a physician has pronounced him dead.

7 If water or other substances are thought to be in the mouth, throat, and air passages, work with the patient in the face-down position with the head low if possible.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONTRIBUTING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E. SMITH, M.D., Secretary

CONCENTRATED OLEOVITAMIN A AND D—

"Fish liver oil, or fish liver oil diluted with an edible vegetable oil, or a solution of vitamin A and D concentrates in fish liver oil or in an edible vegetable oil. The vitamin A shall be obtained from natural (animal) sources and the vitamin D may be obtained from natural (animal) sources or may be synthetic oleovitamin D. Concentrated Oleovitamin A and D contains in each gram not less than 50,000 and not more than 65,000 U.S.P. units of vitamin A, and not less than 10,000 and not more than 13,000 U.S.P. units of vitamin D." U.S.P.

For description and standards see the U.S. Pharmacopeia under Oleovitamins A and D Concentrata.

Actions, Uses and Dosage—See under Vitamin A and D preparations (N.N.R., 1943, p. 605).

WALKER VITAMIN PRODUCTS, INC., MOUNT VERNON, N.Y.

Concentrated Oleo Vitamin A-D Drops Each gram contains not less than 62,500 U.S.P. units of vitamin A and not less than 10,000 U.S.P. units of vitamin D. Natural esters of vitamin A (distilled from fish liver and vegetable oils) plus activated ergosterol in refined corn oil. Flavored with cinnamon.

DEHYDROCHOLIC ACID (See New and Nonofficial Remedies, 1943, p. 322).

The following dosage form has been accepted:
GEORGE A. BREON & COMPANY, INC., KANSAS CITY, MO.
Tablets Dehydrocholic Acid 0.25 Gm.

SODIUM CITRATE (See New and Nonofficial Remedies, 1943, p. 458).

The following dosage forms have been accepted:
BAXTER LABORATORIES, INC., GLENVIEW, ILL.

Sodium Citrate 4% W/V in Distilled Water 25 cc and 50 cc in Centri-Vac containers. A sterile 4 per cent solution of sodium citrate in distilled water.

Sodium Citrate 4% W/V in Distilled Water 50 cc in Transfuso-Vac containers. A sterile 4 per cent solution of sodium citrate in distilled water.

TRYPARSAMIDE (See New and Nonofficial Remedies, 1943, p. 212).

The following dosage forms have been accepted:
MFRCK & CO., INC., NEW YORK.

Ampuls Tryparsamide 1 Gm., 2 Gm. and 3 Gm.

LIVER INJECTION (See New and Nonofficial Remedies, 1943, p. 392).

The following dosage form has been accepted:
THE WARREN-TEED PRODUCTS CO., COLUMBUS, OHIO.
Liver Injection, 10 U.S.P. Units per Cc. 10 cc. vials. Preserved with 0.5 per cent phenol.

NURSING SERVICE IN WARTIME

Nursing service "as usual" is gone for the emergency. The armed forces have a priority on nurses. The remaining nurses must be utilized for all non-military governmental agencies and essential civilian nursing services. The private duty nurses available in the country constitute a small group and there are numerous calls upon them for a wide variety of services. "Luxury" nursing is certainly out for the duration. The nursing section of the Procurement and Assignment Service for Physicians, Dentists, Veterinarians, Sanitary Engineers and Nurses urges that private duty nurses not eligible for military service should be utilized for the care of acutely ill patients, first, in hospitals and, second, in homes. Every nurse should be used on the highest level of skill of which she is capable. A private duty nurse should be assigned to the care of a single patient only when it is impossible to arrange for adequate care by using a part of the service of a nurse who is attending also to other patients. In homes private duty nurses should be employed only when it is impossible to provide enough care through such facilities as are offered by the visiting nurse associations and the hourly nursing services. Another important civilian need is the work of private duty nurses in positions on the staffs of hospitals. Also there are such places as those associated with public health nursing agencies, industry and physicians' offices.

The superintendents of hospitals might give further serious consideration to their utilization of personnel. The tendency should be to utilization of nurses almost wholly by assignment to large groups of patients. The nurse's duties should be evaluated so that the major portion of her time is used in actual nursing care rather than in the serving of meals or in other duties which may be performed by nurses' aides or any of the other auxiliary services that have been developed. In some hospitals already the practice is developing to assign a nurse to the care of a single patient only on the recom-

mendation of the physician in cooperation with the superintendent of nurses and the superintendent of the hospital.

The work of nurses in industry is of increasing significance. The Procurement and Assignment Service has established criteria of essentiality for nurses in industry. Such nurses will not for the present be urged into military service. A nurse who is an industrial nursing consultant, or a state or city health department or a labor department nurse, a supervisor, a staff nurse who is working full time at professional nursing duties or a nurse who is the only full time nurse in an industry, will be considered for the present essential. However, nurses in industry will be expected to limit their activities to professional nursing duties connected with the medical department of the industry with which they are associated. Industries will be urged to utilize existing community services for nursing care if those resources are adequate to meet the needs. Furthermore, industry is urged to avail itself of nonprofessional technical aides whenever possible.

On the medical profession particularly rests the special obligation to utilize the services of nurses in the doctor's office only when absolutely necessary. In each community a local committee of nurses has been established which is to advise in determining offices that need professional nursing services. Physicians who employ a nurse without actual need are requested to release such nurses for use in essential nursing service and to employ other personnel instead. It is realized that the practices of physicians remaining in civilian service have in many instances increased so greatly that there is more need now for efficient office nurses than previously. Even under such circumstances, however, the employment of a nurse not eligible for military service may release an eligible nurse for the armed forces.

Since the Red Cross is charged with the recruitment of nurses for the armed forces, attention might well be given by that organization to the extent to which the nurses now employed by the Red Cross in this country are replaceable by nurses' aides or other partially trained personnel. This applies particularly to the employment of considerable numbers of nurses in blood banks, in teaching of nurses' aides, in mobile units and in other activities in which their time does not seem to be in many instances, wholly utilized.

The problem of supplying nursing personnel has become for the present even more acute than the problem of providing physicians. Under the auspices of the Procurement and Assignment Service for Physicians, Dentists, Veterinarians, Sanitary Engineers and Nurses a number of procedures are in contemplation which it is hoped will yield the names of every woman in the coun-

try ever qualified as a nurse and capable now of being drawn into nursing service. These plans will be announced as rapidly as they are developed. In the meantime a complete enrolment of young women in the U. S. Cadet Nurses Corps and serious consideration to the suggestions here made for the employment of available nurses will do much to help the rapidly growing crisis in the profession of nursing care.

MALARIA AND WORLD WAR II

The progress of medical science and of modern methods of sanitation have thus far proved adequate to prevent major epidemics in this war. In the past, epidemics took a greater toll both among the belligerents and among civilians than did weapons of war. Bubonic plague, cholera and smallpox seem today to belong to a distant past. Minor outbreaks of typhus may be expected among the underfed, vermin infested populations, but these can be readily controlled by methods of delousing, preventive vaccination and general quarantine measures. The most important military medical problem of the present war is malaria.

According to Stitt and Strong,¹ malaria by its prevalence is most important of all diseases in the world today. While the mortality and morbidity caused by this disease cannot be estimated closely, Russell² ventures, on such data as are available, that there are not less than three million deaths from malaria and at least three hundred million cases of malarial fevers each year throughout the world. The dispatch of our troops to highly malarial regions creates an immediate as well as a postwar problem. The problem of malarial epidemics is made acute by the global war. Malaria has always been one of the major scourges of the human race, influencing its health, retarding the progress of nations and affecting the course of many civilizations. Malaria was an important factor in the decline of moral and intellectual vigor which took place in Greece between 500 and 300 B. C. In India it is today the major cause of poverty and of lowered physical and intellectual standards.

Control of malaria among troops on many of our tropical frontiers presents a number of difficult problems. The program, according to Simmons,³ includes such measures as protecting the soldier against mosquito bites, against infection if bitten and against a possibly long and fatal illness if infected. Reliance must be placed on (1) the correct selection of camp sites, (2) the spray killing of adult mosquitoes with pyrethrum extract, (3) chemoprophylaxis with quinine

and atabrine, (4) the use of nets and screens, (5) protective clothing and (6) the organization and instruction of personnel.

The recent advances in malariology involve, according to Russell² the development of synthetic antimalarial drugs, the pyrethrum spray killing of the mosquitoes and methods of species eradication of mosquitoes. Today the Japanese control all the cinchona of the Netherlands Indies. With Germany they also control the Dutch stocks of cinchona alkaloids, together with quinine factories. The Allied Nations had to resort, therefore, to the use of American bark in the form of totaquine. The drug in somewhat larger doses is as effective as quinine sulfate. Quinine, hailed for many years as a specific in the treatment of malaria, is not the ideal drug. Plasmochin, a quinoline derivative is effective against gametocytes, especially those of *Plasmodium falciparum*, but is relatively ineffective against the schizonts of the same species. Atabrine, derived from acridine, resembles quinine in its action against all species of schizonts and in its weakness in affecting any of the gametocytes. All three drugs are, however, alike in their inability in a percentage of cases to cure without the occurrence of relapses and in their failure in safe doses to prevent infection by sporozoites. Not one of the three has been found to be a true causal prophylactic, although each in small doses tends to suppress clinical symptoms.

The Q. A. P. treatment—quinine atabrine plasmochin—as endorsed by the Subcommittee on Tropical Diseases of the National Research Council⁴ represents an efficient treatment for acute malaria. The role of plasmochin, however, is now being subjected to reevaluation because of its toxicity. Totaquine or quinine sulfate (0.64 Gm.) is given three times daily after meals for two or three days until pyrexia is controlled. This is followed by atabrine (0.1 Gm.) three times daily after meals for five days. After two days of rest from medication, plasmochin (0.01 Gm.) is given three times daily after meals for five days. For mild cases atabrine and plasmochin or quinine and plasmochin combinations are satisfactory.

Russell points to the recent eradication of *Anopheles gambiae* in Brazil as the first accomplishment of this kind at any time in any land. Although costly, the experiment establishes for the first time the possibility that in some future time malaria, if not its vector, may be eradicated from the United States.

The problem of immunity to malaria has been the subject of a recent editorial in *THE JOURNAL*.⁵ The malaria therapy of neurosyphilis offered many opportunities for the study of the problem of immunity in malaria. Whether effective serums or vaccines will be produced or whether a new and more effective specific drug will be developed cannot at present be predicted.

DOES AMERICAN MEDICINE NEED A DICTATOR?

THE WAGNER-MURRAY-DINGELL BILL III

Revolutions often produce dictators who rise by force of personality or leadership but usually only after the revolution has run much of its course. The Wagner-Murray-Dingell Bill proposes to supply the dictator for American medicine even before the revolution begins. Compulsory sickness insurance produces the least evils when control of the actual practice of medicine is placed under the democratic management of medical associations. The quality of the medical service under such systems deteriorates least in proportion to the extent to which the establishment and maintenance of standards and quality of medical practice are confided to medical organizations. The authors of S 1161 have overlooked this lesson as they have many others in the field of medical practice. But they had little apparent medical aid in formulating their blueprint for American medicine.

In the Netherlands and Norway the medical profession resisted the attempts of Nazidom to break down the autonomy of the medical profession in spite of severe persecution. In so doing these physicians followed age long professional tradition. The whole body of physicians acting autonomously and democratically is the only institution that has ever succeeded in creating and enforcing standards of conduct not only in practice but in medical education and the operation of medical institutions.

S 1161 makes a shallow pretense of recognizing this fact by proposing to create a committee containing representatives of the organizations concerned with medical practice. This committee is to be purely "advisory," without powers and with indefinite functions. It is to be appointed by the dictator whom it is supposed to advise. Provisions are not suggested whereby state or local professional bodies may exercise judgment and supervision at the only point where such judgment and supervision can be effective.

While the Surgeon General of the United States Public Health Service is proposed as the dictator, it must be assumed that he will follow the pattern of administrative organizations and appoint subordinates responsible to him alone. Does any one believe he can avoid political considerations in making such appointments? He is to have the power to determine who will be specialists, what specialties they will follow and who will remain general practitioners. In fact, the fate of all phases of medical practice is vested in this dictator.

The framers of the proposed law apparently neglected entirely any consideration of the quality of the medical service to be distributed. More than fifty pages of the bill are given to the details of administration and financial arrangements, not one word is printed as to how the standards of medical practice shall be kept

at their present high stage. Mention is not made of measures that might maintain the steady upward progress of those standards that has been characteristic of the period during which their establishment and maintenance have been entrusted to the medical profession.

In the familiar pattern of advocates of compulsory sickness insurance, attention is focused on the political machinery that will distribute medical service, the quality of the service itself receives no notice. Medical care is a service given by physicians, the ability to diagnose and treat disease and protect the health of the public depends on the qualifications of the physician—on his education and training, his integrity, skill and initiative. The Wagner-Murray-Dingell plan is a blueprint for medical revolution, dealing with the sick and with the physicians who care for them as inanimate units to be moved at a dictator's will.

THE UTILIZATION OF HEALTH RESORTS FOR MILITARY RECONSTRUCTION

British physicians have found that health resorts are invaluable as centers for reconstruction of those disabled in war. Already in this war United States Army, Navy and Veterans Administration centers for rehabilitation are being established at many health resorts. The United States Army Medical Corps, for example, has established them at the Ashford General Hospital, White Sulphur Springs, W. Va., the Station Hospital, Camp Carson, Colorado Springs, Colo., the Fitzsimons General Hospital, Denver, the Army and Navy General Hospital, Hot Springs, Ark., the Percy Jones General Hospital, Battle Creek, Mich., the Moore General Hospital at Swannanoa (near Asheville), N. C., the Station Hospital at Davis-Monthan Airfield, Tucson, Ariz., and the Miami Army Air Force Hospital at Miami, Fla.

The Bureau of Medicine and Surgery of the United States Navy has established hospitals at Asheville, N. C., Yosemite, Calif., Glenwood Springs, Colo., and Sun Valley, Idaho.

The Veterans Administration, it is said, is contemplating the establishment of hospitals at such health resorts as Saratoga Springs, N. Y., Hot Springs, Salt Lake, Utah, Hot Springs, S. D., Bay Pines, Fla., and Mineral Springs, Texas.

Examples of satisfactory utilization of health resorts for rehabilitation of our wounded soldiers and sailors are to be found at the Army's Ashford General Hospital at White Sulphur Springs, W. Va., and at the Navy's Naval Convalescent Hospital, Glenwood Springs, Colo.

Typical of the reactions of far sighted medical military officers is the pertinent statement recently made

by a colonel in the Army Medical Corps who is commanding officer of one of the larger Army convalescent hospitals. "From my experience in the last war, and as a medical officer since that time I feel that one of the greatest steps which have been taken in this war has been the effort directed toward the rehabilitation of the injured soldier. I firmly believe that the health resort centers which are being used by the Army are playing an ever increasing part in this program."

American health resorts will play this time, an extremely important part in the rehabilitation of those disabled by the war. This is an important step in the right direction.

Current Comment

MEDICAL AND SOCIAL HISTORIES TO BE SECURED ON SELECTEES

The Selective Service System on October 12 directed local draft boards to gather detailed medical and social histories of registrants classified for induction into the armed forces. Medical field agents attached to each of the country's 6,500 local boards are being appointed to assist. The information gathered will be made available only to examining physicians for the armed services at induction stations. Major Gen. Lewis B. Hershey, director of Selective Service, stated in a bulletin to draft boards that "The Selective Service System and the armed forces want to make certain that the greatest possible care is taken (1) to accept those registrants whose previous medical and social history indicates their ability to adjust themselves under situations of stress, including those who may be termed 'borderline' cases, and (2) to reject those registrants whose condition is such as positively indicates physical or mental breakdown, or failure to adjust themselves to the responsibilities of military service after being inducted." A procedure was also established for the review of the records of men rejected at induction centers or discharged from the armed forces for neuropsychiatric reasons. General Hershey stated that a local board if it is of the opinion that such rejection or discharge was erroneous or the causes for such rejection have ceased to exist, may refer the registrant to the (Selective Service) medical advisory board. A study of 2,500 veterans of this war discharged before August 1942 showed that approximately 40 per cent were discharged because they were suffering from mental and emotional disorders which incapacitated them for military duty, and about 62 per cent of that number became so ill that they had to be hospitalized. General Hershey estimated that approximately 100,000 men will be discharged from the armed forces during this year for "nervous and mental reasons." Under the new program, which General Hershey has termed a medical survey, registrants will be required to fill out two forms—one containing an identity verification

and one detailing the registrant's education. Both forms will be forwarded to state Selective Service directors, who will check the information against state files of persons who have mental diseases and with school authorities. The secondary school systems and state and county health, welfare and social organizations are asked to cooperate.

HOME CARE OF THE TUBERCULOUS

The National Tuberculosis Association has just made available four new pamphlets on "Home Care of Tuberculosis," which should be especially useful in times like these, when the demands on the medical and all of the accessory professions are so great. These pamphlets are directed to the family physician in charge, to the nurses, to the family and to the patient himself. It is recognized that home care is in no sense the equivalent of treatment in a modern sanatorium. However, in times of war it may become the only possible method. The pamphlet for the physician is planned primarily to acquaint him with the nature of the instructions given in the other three pamphlets and also to give him special information regarding tuberculin tests, demonstration of tubercle bacilli and uses of the x-rays. The pamphlet for nurses is devoted primarily to specific instructions regarding nursing care and the protection of the nurse herself. There are also recommended reading lists and answers to questions frequently asked by patients. The pamphlet for the family gives advice regarding preventive methods and also assistance in home nursing. The pamphlet for the patient is most instructive, written in simple language and exceedingly useful. These pamphlets may be obtained from the tuberculosis associations serving in given areas, which obtain the pamphlets at cost from the National Tuberculosis Association.

ARTICLES ON "SPA" THERAPY

In this issue of THE JOURNAL appears the first of a series of articles dealing with the use of health resorts in the treatment of disease. These articles are developed under the sponsorship of the American Medical Association's Committee on American Health Resorts. The material is being prepared by selected authors familiar with the various phases of the subject. This series of articles is particularly timely now. Civilian patients and military casualties alike require medical and hospital care which must be rendered by institutions and professional, technical and other personnel severely restricted under wartime demands for manpower. Every institution suitable for the care of the sick or the convalescent and every therapeutic resource available should be utilized to its utmost efficiency. Spas and spa treatment have had much more extensive attention in Europe than in the United States, yet this country can match every European health resort as to climate and natural characteristics of the waters. In the sharpened focus of wartime needs the Committee on American Health Resorts offers the series of articles beginning this week as a scientific contribution to American medicine and a practical participation in the war effort.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeons General of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession

ARMY

THE SCHICK GENERAL HOSPITAL

The Schick General Hospital, which was formally opened on October 7, is located 3 miles north of Clinton, Iowa. The hospital has a capacity of 1,514 beds and consists of 103 separate structures. The grounds consist of 896 acres of land enclosed by an 8 foot wire fence. There are a chapel, laundry, post exchange, post office, ambulance service, recreational facilities and air conditioned operating rooms. Prior to the formal opening of the hospital there were 2,687 patients admitted (Sept 30, 1943), of whom 674 were operated on. The first patient was admitted on Feb 15, 1943, and on the same day the first surgical operation was performed, on a soldier from this command. On the day of the formal opening there were 1,175 patients in the hospital, representing every overseas theater of operation. The allotment of nurses is 120 and of enlisted men 512. These men are being trained as operating room, x-ray and laboratory technicians as well as ward attendants. The staff of the Schick General Hospital trained the enlisted personnel of the Eighth General Hospital before it was sent overseas and is now training the Ninety-First General Hospital. Major Gen Norman T Kirk, the Surgeon General, has designated the Schick General Hospital as a Neurosurgical Center. The entire project represents an investment of more than \$6,000,000.

The Schick General Hospital was named in honor of Lieut William Rhinehart Schick, first army medical officer to be killed in action during the current war. Lieutenant Schick graduated from the University of Illinois College of Medicine in 1939 and was appointed a first lieutenant, medical corps reserve, April 28, 1941. He was killed when the bomber in which he was flying from the United States to Pearl Harbor was shot down during the raid on Pearl Harbor, Dec 7, 1941.

Following is the medical staff attached to the Schick General Hospital:

Col Dorn F Winn, commanding officer
Lieut Col Lloyd E Gould, executive officer
Lieut Col Benjamin M Brinks, chief of medical service
Capt Wilson C Merriman, executive officer, medical service, and chief, communicable disease section
Capt Harold B Thale, chief of general medical section
Capt Harold Shellow, chief of dermatology section
Capt David W Hilger, chief of neuropsychiatry section
Capt Lewis J Dimsdale, chief of pulmonary allergy section
Capt Emanuel M Rappaport, ward officer, neuropsychiatry section
Capt Ralph W Barris, ward officer, neuropsychiatry section
1st Lieut Manuel Sill, ward officer, neuropsychiatry section
Capt Kermit G Dwork, ward officer, officers' and women's section
Capt Harris V Lilga, ward officer, gastrointestinal section
Capt Max J Klainer, ward officer, cardiovascular section
1st Lieut David Finkelstein, ward officer, cardiovascular section
Lieut Col William J Carrington, chief of surgical service and chief, women's section
Major Moser L Stadiem, assistant chief of surgical service and chief, officers' section
Major Don C Robertson, chief of general surgery section
Capt Willard H Bernhoft, ward officer, general surgery section
Major Joseph E Milgram, chief of orthopedic section
Capt Frank H Stelling, ward officer, orthopedic section
Capt Richard U Peterson, ward officer, orthopedic section
1st Lieut Rolf Johnson, ward officer, orthopedic section, and ward officer, women's section
1st Lieut L A Barrow, ward officer, orthopedic section, and ward officer, women's section
Major Samuel Shenkman, chief of neurosurgery section
1st Lieut Irving J Speigel, ward officer, neurosurgery section
Major Edward N Anderson, chief of urology section
1st Lieut Lloyd L Wells, ward officer, urology section
Major Francis B Blackmar, chief of E E N T section
Capt Richard W Garlachs, assistant chief of E E N T section
Major Daniel R Mishell, chief of septic surgery section

Capt Leo C Harris, ward officer, officers' section, and consultant on thoracic surgery

1st Lieut Solomon Winokur, chief of physical therapy section

Capt Jack Milowsky, chief of anesthesia and operating section

Major Henry Edstrom, chief of x-ray service

Capt Julius Rosenthal, chief of laboratory service

1st Lieut Harney M Cordua, assistant, laboratory service

Capt Alonzo H B Drake, chief of outpatient service

Major Sidney Olans, registrar

Lieut Col I J Frisch, public relations officer

Major E G Johnson, commanding officer, medical detachment, medical department and director of training division

FOREIGN MAPS WANTED FOR MILITARY USE

The Army Map Service, Corps of Engineers, U S Army, is seeking large scale maps (1:1,000,000 or larger) of areas outside the United States and Canada, road maps, topographic and geological maps, detailed topographic maps, city plans and port plans, as well as guide books and travel folders, gazetteers, postal guides and important atlases, aerial photographs, survey notes and geodetic control data (the more recently issued the better). If any of this material is not available as a gift, it must be specified as such, reproduction will be made and the originals returned to the owner. The Army Map Service does not need United States government issuances and such obvious sources as the National Geographic Society, as this material is already on file. Information concerning available material of this kind should be submitted to the branch office in one's locality.

Chicago Library Branch, Army Map Service, 79 West Monroe Street, Chicago, attention Miss Barbara C Todd, phone Central 3240

New York Library Branch, Army Map Service, 1270 Sixth Avenue, New York City, attention Miss Violet Klipell, phone Circle 6 4250

San Francisco Library Branch, Army Map Service, 74 New Montgomery Street, San Francisco, attention Capt Norman F Develyn, phone EXbrook 2009

SOLDIER'S MEDAL AWARDED FOR HEROISM AT ALGERIAN BASE

Twenty-two medical officers and enlisted men of the Army Medical Corps and two officers of the Air Corps were recently awarded the Soldier's Medal for outstanding heroism during an explosion of bombs on June 26, 1943 at an Algerian base under the command of Major Gen James H Doolittle, commanding general of the Northwest African Strategic Air Force, according to an announcement made by the War Department, Washington, D C, October 10. When a number of bombs exploded at an ordnance area these officers and enlisted men aided in removing the injured and placing them in ambulances and in checking the spreading flames, in spite of the danger of continued explosion. The citation states: 'The heroic action and valiant work continued until they were forced to withdraw by superior authority. The heroism, valor and courage in the face of great danger reflects credit on themselves and on the armed forces of the United States. The medical officers decorated are Frederick D Koehne, Major, M C Orlind, Iowa, Raymond J Beal, Captain, M C Kansas City, Mo, Milton J Laiden, Captain, M C Philadelphia, Theodore C Papermaster, Captain, M C St Cloud, Minn, Wayne W Warren (dentist), Captain, M C Fort Dodge, Ia, James L Smitherman, First Lieutenant, Air Corp, Oregon Falls.

FIRST LIEUTENANTS IN NURSE CORPS NOW MAY BE ASSIGNED TO WARD DUTY

The War Department announced on October 14 that members of the Army Nurse Corps now are eligible for more rapid promotion under a new table of organization which makes first lieutenants available for ward duty in addition to second lieutenants. Heretofore nurses in the grade of first lieutenant virtually were limited to duty in the chief nurse's office or were placed in charge of an operating room or of nurses quarters. However, because of the importance of bedside care of wounded and sick, and to give qualified nurses a chance for advancement the new organizational setup was effected. Under it first lieutenants may be put in charge of wards, sections or complete nursing services such as chief of surgical nursing service, chief of medical nursing service, chief of psychiatric section, orthopedic section or of single similar wards. At the same time it was announced that nurses over 45 are not being sent overseas for duty with the armed forces but are being given the opportunity of caring for battle casualties in general hospitals in the United States, to which wounded are being sent for treatment with the least possible delay. It was announced too that nurses who return from a theater of operations and desire further overseas duty may, after six months in the United States, be considered for reassignment overseas provided they are physically qualified.

AMERICAN MEDICAL SOCIETY IN ENGLAND

At the suggestion of Brig Gen Paul R Hawley, chief surgeon in the European theater of operations, a medical society was organized for the members of the Medical Corps in that theater. The society has been named the American Medical Society, ETO. All officers of the U S Army Medical Corps are automatically made members of the society. The purpose of the organization is to provide a means for an exchange of current professional experience and intelligence of investigative work carried on by the members of the U S Army Medical Corps in this theater. Members of the Medical Corps of the several Allied Nations are invited as guest speakers. Monthly meetings are being held at the various general hospitals with sessions limited to one day. Subjects of interest to all branches of the Medical Corps are presented at each meeting and various problems are demonstrated by medical exhibits in much the same manner as is done at medical meetings held in the United States.

The first meeting, which was held at the 298th General Hospital on June 23, was addressed by General Hawley. At this meeting the following officers were elected: Lieut Col Robert Zollinger, M C, Fifth General Headquarters, president; Lieut Col William F McFee, M C, Second Evacuation Hospital, vice president; Major Clifford Graves, M C, Third Auxiliary Group, secretary-treasurer; Col E J Tracy, M C, Eighth Air Force, member at large; Lieut Col R S Muckenfuss, M C, First General Medical Laboratory, member at large.

Other meetings have been held at the Thirtieth General Hospital and the Second General Hospital.

ARMY GENERAL HOSPITAL NAMED FOR ARMY NURSE

The War Department announced on October 16 that an army general hospital (the former Chicago Beach Hotel) Chicago, has been named the Ruth M Gardiner General Hospital in memory of the first army nurse confirmed as killed in a theater of operations in this war. Second Lieutenant Gardiner was a member of the Army Nurse Corps attached to a medical squadron of the Army Air Forces and was killed in a plane crash in July 1943 at Nankeah Alaska while serving as an air evacuation nurse. Lieutenant Gardiner graduated with the second class of flight nurses from the School of Air Evacuation Bowman Field Ky on Feb 18, 1943 and left there for evacuation duty with the Eleventh Air Force in Alaska on April 22.

FIRST FLIGHT NURSE RETURNS FROM COMBAT ZONE

According to the War Department, Second Lieut Henrietta Richardson was the first flight nurse to return to the United States from a combat zone. Serving with an Army Air Forces Air Evacuation Unit in North Africa, she found that "the morale factor is an important part of the flight nurse's job." A former airline stewardess, Lieutenant Richardson was stationed with the twenty-four other flight nurses in her squadron at the Maison Blanche airport near Algiers. Her unit flew shuttle routes from Maison Blanche into Tunisia, Tellerghma and Youks-Leban and back to Algiers, Oran and Casablanca. From March 12, 1943 to May 12, 1943 she accumulated 132 hours of combat evacuation flying. Lieutenant Richardson is a graduate of St Vincent's School of Nursing, Los Angeles. She entered the Army Nurse Corps on Sept 14, 1942 and left the United States on Christmas day of that year for overseas assignment.

SURGEON GENERAL OF BRITISH ARMY FETED

Major Gen Norman T Kirk, surgeon general of the United States Army, gave a dinner on October 12 at the Mayflower Hotel Washington, D C, in honor of Lieut Gen Sir Alexander Hood, visiting surgeon general of the British army. Other distinguished guests who attended the dinner were Rear Admiral Luther Sheldon, Major Gen R W Styer, Major Gen Leroy Lutes, Major Gen Shelley U Marietta, Major Gen George F Lull, Major Gen Albert W Kenner, Major Gen Merritt W Ireland, Brig Gen Hugh J Morgan, Brig Gen Raymond W Bliss, Brig Gen Fred W Rankin, Brig Gen George Dunham, Brig Gen Russell Reynolds, Brig Gen Raymond A Kelser, Col Arden Freer, Col Tracy S Voorhees, Col Henry C Chenault, Col Arthur B Welsh, Col Frank S Gillespie, Col R C McDonald, Col James R Hudnall, Col Stanhope Bryne-Jones, Col Paul I Robinson, Col Marion F Du Frenne, Col Leonard Rowntree, Col Frank Strong, Col Rex Diveley, Col George R Callender, Col James R McDowell, Col William E Shambora, Col Silas B Hays, Lieut Col Robert John Carpenter, Major C R Durnford, Major Robert S Gearhart, Dr Warren F Draper, assistant surgeon general of the United States Public Health Service, and Norman Davis.

PHYSICAL DISABILITY DISCHARGES OF THE ARMY

For the twenty month period ended July 31, 1943 discharges from the Army of the United States for physical disability totaled 208,296 men according to an announcement made by the War Department recently. While more than half of these discharges were of a miscellaneous nature, the larger classifications in order were neuropsychiatric, heart disabilities, impairment of vision, tuberculosis and disabilities resulting from wounds. According to statistics from the Office of the Surgeon General, the percentage of disability discharges resulting from neuropsychiatric causes have increased within the twenty month period. Major Gen Norman T Kirk, Surgeon General, stated that "the Army has not granted disability discharges to any men who could be used effectively in the military prosecution of this war."

MEDICAL CORPS OFFICERS NEEDED FOR SERVICE IN PARACHUTE UNITS

The War Department has announced, according to the *Army and Navy Journal* of October 2 that medical corps officers in company grades and not over 32 years of age are needed for service in parachute units. Volunteers on acceptance will be sent for training to the Parachute School Fort Benning Georgia. Physical standards are those prescribed in section V War Department Circular 155 of 1942.

EVACUATION HOSPITAL IN ITALY BLOWN DOWN DURING STORM

As a result of a heavy rain and wind storm which leveled every tent in a great field evacuation hospital with the Fifth Army in Italy within five minutes, 1,000 sick or wounded soldiers had to be transferred to a nearby tobacco warehouse, according to an item published in the *Chicago Tribune*, October 13. Lieut. Col. Phil A. Daly of Chicago, who superintended the removal, is director of the hospital staff, most of whose members came from the Michael Reese Hospital, Chicago. Two hundred of the patients most seriously ill were moved to a big barn and hayloft across the field. All this was accomplished in less than two hours. Colonel Daly stated that "It was really a mess, with mud over everything. How we got them all out of there I don't know. If we had planned this it would have taken two days. The storm was almost a tornado. It blew over an x-ray generator." Capt. Philip Marcus of Chicago, a member of the medical staff, said that one operation was finished under the operating table by flashlight after the tent blew down.

U S ARMY TRANSPORT SHAMROCK (EX AGWILEON) DESIGNATED AS HOSPITAL SHIP

The War Department, Washington, D. C., in General Orders No. 52, states that on Aug. 3, 1943 the United States Army transport *Shamrock* (ex *Agwilcon*) was designated as a military hospital ship, in accordance with international practice, as set forth in the provisions of the Hague Convention X of 1907. In the future the United States Army hospital ship *Shamrock* will be operated in accordance with the provisions of applicable treaties. Notification of this designation was delivered through channels to the German, Hungarian, Bulgarian and Rumanian governments on August 12. The ship's master of this and all other United States military hospital ships will at all times maintain sufficient copies of this general order for presentation to any authorized agent of an enemy belligerent who may require it for inspection.

INDIANA UNIVERSITY MEDICAL CENTER HOSPITAL UNIT ARRIVES IN ENGLAND

According to word recently received at the Indiana University Medical Center, Bloomington, members of the medical division of General Hospital 32, organized and sponsored by the Indiana University Medical Center, have arrived in England following field training at Camp Bowie, Texas. The unit is composed of doctors, dentists and nurses from Indiana, who were inducted at ceremonies held at the Medical Center on May 13, 1942. During the organization of this unit it was planned to include 700 persons, including 120 nurses, but, since the unit was divided after arrival at Camp Bowie, the information received at the Medical Center did not state how many of the original complement were included in the group arriving in England.

AIR SERVICE COMMAND INSTALLS NEW TYPE X-RAY MACHINE

The latest type, money-saving x-ray machine, equipped with a photoröntgen unit, was recently installed at the Air Service Command, Patterson Field, Fairfield, Ohio. The old style x-ray machine with 14 by 17 inch plates was expensive to operate, while the new machine produces pictures only 5 by 7 over all at a nominal expense. The new machine has film specially mounted on reels requiring a short twist of a dial for a change, the procedure being the same as a roll of film in a camera. A special type tube is used also, which permits constant usage without burning out. This procedure makes it possible to x-ray the entire personnel of the Air Service Command and Patterson Field, 28,000, at the rate of 2,000 weekly. Col. John M. Hargreaves is chief of the medical section of the Air Service Command at Patterson Field.

FIRST CLASS OF WACS ENTERS ARMY MEDICAL TECHNICIAN SCHOOL

According to the War Department, 145 enlisted women of the Women's Army Corps began training on September 10 at the Army-Navy General Hospital in Hot Springs, Ark., as medical, surgical, x-ray, dental and laboratory technicians to serve with the Army in hospitals in this country and overseas. In addition to the enlisted Wacs, twelve WAC officers also began the course in order to take over future training and administrative staff jobs at the school, thus releasing medical corps men. The course for x-ray, dental and laboratory technicians will last three months, that for medical and surgical technicians, two months.

PHYSICAL EFFICIENCY AMONG SOLDIER TRAINEES SHOWS IMPROVEMENT

The War Department, Washington, D. C., announced on October 2 an average improvement of 21 per cent in physical efficiency among soldier trainees in the first term of participation in the Army Specialized Training Program. Performances were recorded in seven events among 2,557 trainees at the twelve institutions in which the program had its inception, both at the start of the course and approximately three months later. Gains in various events ranged from 6 to 30 per cent. Trainees devote six hours weekly to physical training.

ARMY PERSONALS

Col. Crawford F. Sams, former chief surgeon in the Middle East Theater of Operations, has returned to Carlisle Barracks, Pennsylvania, to become director of military art at the Medical Field Service School, according to an announcement by the War Department, September 30. Colonel Sams went overseas late in 1941 to help build bases and establish medical service in the Middle East for the U. S. Army personnel. He was in Tobruk when it was bombed eleven times in twenty-four hours and was stationed for a time at Cairo. Later he was assigned to General Montgomery's British Eighth Army as an observer and was with the group when it was attacked by Marshal Rommel's forces at Gozzala in May 1942. Colonel Sams graduated from Washington University School of Medicine, St. Louis, in 1929. Colonel Sams was assistant department surgeon and for a time acting department surgeon in the Panama Canal Department from 1937 to 1939 and was instructor in logistics and medical service in the Infantry School from 1939 to 1941. During 1935 and 1936 he was director in the Department of Military Art at the Medical Field Service School, the same position to which he has just been assigned. Colonel Sams has been awarded the Order of the British Empire, Legion of Merit and Star of Africa, as well as American Defense ribbons, the American Victory medal from the last war and the Middle East-North African campaign ribbon.

According to the *Franklin (Ind.) Star*, September 23, word was recently received that Capt. Frank P. Albertson, formerly of Trafalgar, Ind., is confined to an evacuation hospital in the South Pacific with injuries received on Guadalcanal, September 3. Captain Albertson, who graduated from the Indiana University School of Medicine, Indianapolis, in 1934, for sixteen months was stationed on various Hawaiian Islands after entering the service but was dispatched by plane on a mission to the South Pacific in July 1943.

According to the *Auburn (Calif.) Journal* of August 28, Col. William H. Smith recently assumed the post of commanding officer of the U. S. Army General Hospital in Auburn, Calif. Colonel Smith graduated from Washington University School of Medicine, St. Louis, in 1905. After graduating from the Army Medical School he was commissioned in the regular army medical corps in 1909. He served with the American expeditionary forces in Vera Cruz in 1914.

Lieut. Col. Loyal Davis, consultant to the Army's chief surgeon, was in Chicago recently on a brief leave after a full year in the European theaters of war.

NAVY

STREETS NAMED IN HONOR OF MEDICAL DEPARTMENT PERSONNEL

The Bureau of Medicine and Surgery has named nine streets on the reservation of the new U S Naval Hospital, Dublin, Ga, for medical department personnel killed while on active duty since Dec 7, 1941, according to the *Army and Navy Journal* of September 11.

Gendreau Circle honors the memory of Capt Elphage A M Gendreau (MC) USN who was killed in combat action in the South Pacific on July 21, 1943, Captain Gendreau was force surgeon of the Pacific Fleet Blackwood Drive is named for Comdr James D Blackwood (MC), USN, senior medical officer of the U S S *Imcommes*, which was lost the night of Aug 8-9, 1942 Johnson Drive, Alexander Drive and Crowley Avenue are named for three officers who were killed in action at Pearl Harbor on Dec 7, 1941 They were Comdr Samuel E Johnson (MC) USN, Lieut Comdr Hugh R Alexander (MC), USN, and Lieut Comdr Edward E Crowley (DC), USN.

Evans Avenue will honor Lieut Comdr Edward E Evans (MC), USN who was killed during action in the Solomons on Dec 12 1942 Neff Place will be in memory of Lieut Comdr James B Neff (MC), USN Commander Neff was senior medical officer of the U S S *Jumeau*, which was sunk on Nov 13, 1942 in the South Pacific Trojakowski Avenue and Morrow Place will honor Comdr W C Trojakowski (DC), USN, killed in action in the South Pacific on June 12, 1942, and Lieut (jg) Edna O Morrow, Nurse Corps, U S N, who was killed in an aircraft accident near San Francisco, Jan 21, 1943, while returning from the Pacific war zone.

NAVY DOCTORS REMOVE LIVE SHELL FROM HIP OF WOUNDED ENLISTED MAN

While standing at his post aboard an American warship in the South Pacific, Allen L Gordon, a fire controlman third class of Rock Island, Ill, was struck below the left chest by a 20 millimeter antiaircraft shell, which pierced his intestine and lodged in his left hip The shell did not explode An emergency operation was performed on board the battleship to repair his intestinal tract Later the sailor was taken ashore and, although the navy hospital at this outpost was still under construction, under the direction of Lieut Comdr Harold W Jacob, formerly on the staff of the Western Pennsylvania Hospital, Pittsburgh, several days were spent in trying to locate the "dud" by x-ray When the shell was located, a steel plate was prepared and the operation was performed in a few minutes by Lieut Comdr Jesse R Griffith and Lieut William C Wycoff, both from the Western Pennsylvania staff in Pittsburgh Although infection set in, Gordon was strong enough eventually to return to the United States, where treatment was continued.

BASE AND MOBILE OPTICAL UNITS

The Bureau of Medicine and Surgery, Washington, D C, in its weekly release dated October 11, states that a number of optical units have now been organized and equipped by the bureau Its mission is to provide emergency spectacle replacement and repair service, without charge, to all naval personnel in combat areas and other places not accessible to civilian facilities, also to supply urgently needed corrective spectacles to naval personnel under like circumstances There are two types of these units, base and mobile, and both are prepared to provide corrective or replacement lenses sufficiently accurate to meet the needs of combat personnel The base unit will be in a relatively fixed installation, while the mobile unit can be easily transported from place to place Each unit is a component of the Medical Department of the Navy and carries technical personnel, officer and enlisted, selected on the basis

of previous optical service and special training The units will operate under the orders of the commanding officer of the area in the same manner in which naval base hospitals and naval mobile hospitals are now being operated.

HIGH SPEED FLYING AMBULANCES FOR NAVY AND MARINE CORPS

According to a recent release from the Postwar Aviation Bureau, Chicago, a new high speed flying ambulance for navy and marine corps use, known as the Howard-Nightingale, is a small transport which will carry two badly wounded men in wire stretchers and a crew consisting of pilot, co-pilot and nurse and can operate from bases as far as 200 miles from battle zones It is manufactured by the Howard Aircraft Corporation of Chicago and St Charles, Ill, and is said to have the speed of at least 2½ miles a minute It is capable of landing in almost inaccessible spots, picking up the wounded and carrying them speedily to well equipped hospital units without shock or further injury to broken bones The first of these ambulances are either on their way across the sea or have reached combat zones.

COMMANDER BARTHOLOMEW W HOGAN RECEIVES SILVER STAR AWARD

The Navy Department, Washington, D C, announced on September 10 the presentation of the Silver Star Medal to Comdr Bartholomew W Hogan (MC), USN, by Secretary of the Navy Frank Knox Commander Hogan's award was accompanied by the following citation:

For conspicuous gallantry and intrepidity in action as Senior Medical Officer of the U S S *Wasp* when that ship was torpedoed by enemy Japanese submarines on Sept 15 1942 With his carrier swept by flaming gasoline and rocked by explosions Commander Hogan despite his own serious wounds worked tirelessly caring for the injured until forced to abandon the stricken ship His outstanding professional skill and heroic devotion to duty throughout these perilous hours were in keeping with the highest traditions of the United States Naval Service.

Commander Hogan, who graduated from Tufts College Medical School, Boston, in 1925, in which year he entered the service, is now on duty at the Bureau of Medicine and Surgery, Washington, D C.

FIRST WOMAN MEDICAL OFFICER TO BE GIVEN RANK OF LIEUTENANT COMMANDER

Lieut Comdr Catherine Louise McCorry, MC-V(S), (F), USNR, is the first woman medical officer to be given this rank since the Navy has accepted women doctors, according to the Bureau of Medicine and Surgery in its weekly release dated October 4 Lieutenant Commander McCorry graduated from Loyola University School of Medicine, Chicago, in 1930 and has been employed by the department of public health in Illinois as a psychiatrist and internist since completion of her training It is expected that she will be ordered to active duty on or about October 25.

COMPLETE INSPECTION OF ALL NAVAL CONVALESCENT HOSPITALS

The *Army and Navy Journal* of September 25 states that Rear Admiral Luther Sheldon Jr (MC), USN, assistant chief of the Bureau of Medicine and Surgery and Comdr F J Braceland (MC) USNR neuropsychiatry section, have completed an inspection of all naval convalescent hospitals in the western and southwestern parts of the country As a result of this trip Admiral Sheldon is convinced that with some additional expansion the Medical Department of the Navy is in a position to handle any burden that may be thrown on it by reason of the war in the Pacific.

MISCELLANEOUS

WARTIME GRADUATE MEDICAL MEETINGS

The chairman of the committee in charge of Wartime Graduate Medical Meetings has prepared a pamphlet indicating the nature of the organization, the regional committees, the areas of activity, a report of the undertakings of various regional committees, a list of the national faculty and the subjects discussed, and some answers to questions that have been propounded in largest numbers. This manual is exceedingly useful to all those who are participating in this important graduate education. Copies may be obtained by addressing Dr. Edward I. Boritz, 4200 Pine Street, Philadelphia.

PROMINENT PROFESSORS OF MEDICINE IN ARGENTINA DISMISSED

As a result of the Ramirez government's order that all office holders who signed a recent prodemocratic manifesto be ousted, a number of professors of the highest standing in the universities of Argentina have been affected. Hundreds of medical students are reported to have crowded into the operating theater to hear the world famed Dr. Bernardo A. Houssay deliver his final lecture, and hundreds of other students were said to have jammed into the final lecture of Prof. Alejandro Ceballos, another well known Argentinian. Lectures by Dr. Nicolas Romano and Dr. Marmore E. Castex at the Hospital Nacional de Clinicas also attracted hundreds of Argentinians, who might otherwise have been unable to demonstrate their opposition to the nation's neutrality and its military government. Ramirez is understood to have stated that, besides being dismissed from public office, these men will not be allowed to leave the country.

COMPACT X-RAY UNITS FOR AIRCRAFT CARRIERS

Facilities for instant x-ray diagnosis of wounds and injuries are now available to airmen based on many U. S. aircraft carriers on the high seas. These war tailored x-ray units, developed and manufactured by the Kelley-Koett Manufacturing Company, Covington, Ky., are being installed in the Kaiser built carriers. The carrier borne unit includes a "rotary converter" to transform the ship's direct current to alternating current for x-ray uses. Many war plants use this specially designed x-ray equipment to detect flaws in vital metal parts before they are made into tanks, planes and guns. Major Gen. Norman T. Kirk, Surgeon General of the Army, who recently made a personal inspection of the Kelley-Koett Manufacturing Company, commended the workers for meriting the Army-Navy E and said "The x-ray machines you are making are used to salvage men during a time when weapons of destruction are being made for killing."

MEDICAL AND SURGICAL RELIEF COMMITTEE OF AMERICA

The Medical and Surgical Relief Committee of America, with headquarters at 420 Lexington Avenue, New York City, is conducted by a nationwide group of physicians and surgeons to send medical aid to the armed and civilian forces of America and the Allies. In response to a request from the First Group Civil Air Patrol of Cleveland the committee is donating to this unit emergency medical supplies to supplement its minor first aid equipment. Packed in portable cases, the committee's contribution includes sulfonamide drugs, anesthetics, antiseptics, an instrument roll for minor surgery and many other essential medical items. These items will be used in ambulances or transported by airplane directly to the scene of disaster. According to Dr. J. P. Hoguet, medical director of the committee, over \$1,500 has been donated by the committee to civil air patrols. Emergency medical field sets and other supplies have also been sent to C. A. P. units in Falmouth, Mass., Reno, Nev., Beaumont, Texas, and Pascagoula, Miss.

WOMEN PHYSICIANS NEEDED IN ARMY AND NAVY MEDICAL CORPS

A nationwide campaign will be opened on December 4 by the American Women's Medical Association to stimulate applications by women physicians for commissions in the Army and Navy Medical Corps, according to an item in the *New York Times*, October 5. The drive, which will be under the direction of Dr. Zoe Allison Johnston, Pittsburgh, national president of the association, will start its campaign at the annual meeting of the organization's executive board in Pittsburgh. The medical department of the Navy is reported to have openings in each of three ranks, lieutenant junior grade, lieutenant senior grade and lieutenant commander, and the major demand is for women laboratory physicians, psychiatrists and pathologists. Dr. Eva Caicy, president of the Pittsburgh Women's Medical Society, stated that, "While there is no present surplus of women doctors, there is available a valuable supplement to the male contingent."

SEDATIVES DONATED TO RECOVERY CENTERS

Four thousand capsules of sedatives have recently been donated to the War Shipping Administration for use in recuperation centers in England and North Africa. Dr. Joseph P. Hoguet, medical director of the Medical and Surgical Relief Committee of America, pointed out that many seamen resting in War Shipping Administration convalescence posts abroad have manned ships loaded with explosives, many more have traveled through waters infested with submarines, and others are survivors of torpedoed merchant vessels. Many of these men are tense from the memory of grim ocean crossings, from the shock of combat or shipwreck and cannot sleep. These mild sedatives will relax strained nerves and ensure them a normal night's rest.

Sixteen large emergency medical field sets consisting of two valise sized cases for use by doctors for wounded and ill merchant seamen were also donated by the committee. These sets contain drugs, antiseptics, bandages, sutures, syringes, and minor surgery instruments to meet any emergency. They are carefully packed for immediate use, are portable, and can be carried directly to where the casualties are.

BRIG GEN JAMES S. SIMMONS
AWARDED SEDGWICK MEDAL

Brig. Gen. James S. Simmons, director, Preventive Medicine Division, Office of the Surgeon General, Washington, D. C., was awarded the William Thompson Sedgwick Memorial Medal during the annual meeting of the American Public Health Association in New York, October 12. The medal is awarded each year for distinguished service in public health. Charles-Edward A. Winslow, Dr. P. H. and winner of the Sedgwick Medal in 1942, presented the award. Brigadier General Simmons graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1915 and entered the medical corps as a first lieutenant in 1916. He has devoted more than a quarter of a century to the upbuilding of public health laboratory service in the military establishment. At the outbreak of the present war, Brigadier General Simmons was entrusted with the organization of a division of preventive medicine in the Office of the Surgeon General.

PRISONER OF THE JAPANESE

According to a recent item in the *Denver Post*, 1st Lieut. William DeBacker, who was taken prisoner by the Japanese in the Philippine Islands, sent a message to his wife that he is in a prison camp in the Philippines and is well. Lieutenant DeBacker, who practiced medicine in Pueblo, Colo., before entering the service, graduated from the University of Colorado School of Medicine, Denver, in 1940.

PUBLIC HEALTH UNDER HITLER

NDF of September 3 states that besides the other welfare measures taken by the party of the state, medical help is of great importance to the civilian population after air raids. An important field of activity has thus arisen for the DRK, reports Heudth, oberstfuhrer of the DRK in the periodical *Das Deutsche Rote Kreuz*. In raided areas the Red Cross disposes of thousands of Red Cross nursing auxiliaries who have been trained in first aid and men and women assistants besides nurses working in hospitals. They are always on call for an emergency, mainly for the medical patrols which set out immediately after an air raid.

When heavy destruction is caused among dwellings, doctors' practices are frequently destroyed too, so that medical attention for the sick and injured may be difficult for the first few hours and days after a raid. That is where the DRK patrol service comes in. The Red Cross emergency cars or simple ambulance cars, staffed with a doctor and several Red Cross assistants, cruise through the streets as "mobile ambulances" to give first aid to persons suffering injury during the raid. The seriously injured are often taken to hospitals immediately. Of great value too is the help your neighbor scheme of all members of the Red Cross, who are trained in first aid and who render effective aid to the injured while the raid is still in progress and thus prevent their condition from becoming more serious.

Medical stations have been set up in the big public air raid shelters to attend to the sick and injured. They are mainly staffed with women assistants of the Red Cross. Red Cross personnel also serve on evacuation trains from the moment they leave the raided areas until they arrive in the reception areas. In order to assure on an even wider scale the medical care of the civilian population hit by the air war, there is a continuous flow of fresh forces from the headquarters of the DRK to action stations. As the motorized units, such as the Red Cross emergency cars, busses and ambulances increase, all over the reich persons with special aptitude for such work form special standby units and after a specialized training of several months, are sent to the raided areas. Well timed and generous planning is combined with constant readiness of the Red Cross forces to do their utmost. The sacrifices which this war demands of the civilian population are hard and painful.

Radio Hilversum (Dutch home service) of September 12 states that for the third time since its foundation the Medical Front held a national convention in Utrecht. The first speakers were Dr Keyer, head of the Department of Public Health, and Dr Goette, leader of the Medical Front. After them the leader spoke. From his speech it appeared that some 500 doctors are required to go to Germany and are reluctant to go. Among other things Mussert said "If we consider that it is the duty of every European to fight for the future of Europe, why should those 'gentlemen' be allowed to stand aloof? They are always coming with touching stories about the fate of our workers in Germany. If they are too small minded to help the Germans, why don't they go and help their fellow countrymen in Germany? For this reason I assure you, my comrades, that I shall do everything in my power to send 500 or 1,000 doctors to Germany."

Algemeen Handelsblad of July 2 gives the reasons why those doctors who have protested against the recent decrees imposed on them by the reich commissar have been put into concentration camps. The cause was their first letter of protest and not the second.

Measures have been taken by the sicherheitspolizei against the demonstrators, whose conduct must be considered serious. They are now in concentration camps, where they can ponder on the shortcomings of their misdeeds. They are awaiting their punishment. In addition their property will be confiscated in accordance with paragraph 1 of order number 33 of 1940.

"Some of these demonstrating doctors have chosen to disappear. Their surgeries have been sealed by the sicherheitspolizei. This incident also appears to be evidence of the constant collaboration between certain intellectual circles and Orange-Bolshevik messengers, which was proved recently in Amsterdam during the proceedings against the instigators of the attack on the population register.

"It is not at all a question here of the second letter sent to the reich commissar, which the English radio announced recently even before the letter had reached the addressee. In reality a few similar letters arrived only a few days later. This showed that the writers of the letter had been listening to the English broadcasters or had let themselves be guided by a group acting according to instructions from the London emigre clique. For these persons no one will be surprised that such actions will have very unpleasant consequences for the writers concerned."

Reich Health Leader Dr Conti, according to DNB of July 31, has ordered all members of the medical professions, especially doctors, dental surgeons, dentists and nature cure practitioners who use X-ray equipment, to register with the competent reich defense commissioner, who will pass on the details to the office of the chief medical officer. X-ray apparatus and tubes which are not in use at present must be registered by the respective owners. This does not apply to manufacturers and dealers. Any change of ownership after registration must also be reported. Registration must be made not later than September 1.

Gardist, Bratislava, August 8, writes. At the invitation of the Slovak University Students Association, German soldier students from the front who had been seriously injured came to Priestany some days ago. When I spoke with them about the fall of Orel and Catania they expressed neither apprehensions nor doubts but only dislike of journalistic expressions such as "successful disengagement from the enemy" (erfolgreiche Absetzung vom Feinde) or "disguised maneuvers" (maschierte Manover), which fail to convince.

According to *Der Neue Tag* of August 7 the municipality of Olomouc has built a new emergency hospital in Blasius Square in addition to that already existing in the Neugasse (New Street). The new hospital, which will be for scarlet fever, diphtheria and similar diseases, is a two story building and has the most up to date medical equipment. It is run by a senior doctor assisted by two women doctors. The hospital holds 120 patients and is the largest in northern Moravia.

The *Journal officiel*, August 20, published act number 430, dated July 29, 1943, enforcing the act of Dec 16, 1942 on the premarital medical examination certificate. The prospective husband and wife are from now on both under compulsion to produce a prenuptial certificate not more than one month old, simply stating that the applicant was medically examined without any other indication.

Norwegian nurses are now being hard pressed to "do their duty," which means service at the front, according to *Stockholms-Tidningen* of September 8. The demand for nurses is urgent, especially on the arctic front, and the Germans want Norwegian nurses to take over the whole of the nursing service there.

According to NPD of July 31, German medicine has made the surprising discovery that a number of dangerous blood diseases can be cured by a systematic denial of vitamins to the patient. This new treatment opens up entirely new perspectives to medical science.

Zora of July 23 states that the incidence of spotted typhus this year is double that of last year. The cases are mainly among Gypsies and are in Deli, Orman Rhodopi, Yambol and the new territories. The chief of the Public Health Directorate has formed flying detachments for combating the disease.

According to NPD of September 6, exports of the German pharmaceutical industry will probably increase by 36 per cent in 1943 compared with the previous year. German medical preparations are at present being supplied to thirty-two different countries.

ORGANIZATION SECTION

THE VOCATIONAL REHABILITATION ACT AMENDMENTS OF 1943

PREPARED BY THE BUREAU OF LEGAL MEDICINE AND LEGISLATION,
AMERICAN MEDICAL ASSOCIATION

The President on Oct 9, 1942 sent a special message to the Congress recommending an expanded program for civilian vocational rehabilitation. This recommendation became an actuality with the enactment by the Congress of the Barden-LaFollette bill, so called because of its sponsorship by Representative Barden of North Carolina and Senator LaFollette of Wisconsin. It was approved by the President on July 6, 1943 as Public Law 113, Seventy-Eighth Congress. Now regulations have been promulgated by the Administrator of the Federal Security Agency under which the provisions of the new law will be made effective.¹

IN GENERAL

Broadly stated the recently enacted law contemplates a continuation on an expanded basis of the general pattern of a federal-state program for civilian vocational rehabilitation that has been functioning since 1920. An Office of Vocational Rehabilitation has been set up in the Federal Security Agency to administer the program on the federal level. On a state level it will be administered by state boards of vocational education or by state rehabilitation commissions if in existence on July 6 and if such state boards delegate to the commissions the duty of so functioning. If, under the laws of any state, commissions for the blind or other agencies which provide assistance or services for the adult blind are authorized to provide them vocational rehabilitation, then such a procedure will be continued.

The new law places no ceiling on the annual federal sum that can be made available except the most elastic ceiling of "such sums as may be necessary." The term "rehabilitation services" and the term "vocational rehabilitation" are defined to include any services necessary to render a disabled individual fit to engage in a remunerative occupation. Physical restoration of the disabled will constitute a major objective of the expanded program. A state plan to be approvable must provide that vocational rehabilitation will be made available only to classes of employable individuals defined by the Administrator of the Federal Security Agency, including any civil employee of the United States disabled in the performance of his duty and any war disabled civilian whose disability results, without personal misconduct, from disease or injury, or from an aggravation of a preexisting disease or injury, incurred in line of duty while serving at any time after Dec 6, 1941, and prior to the termination of the war.

- 1 In the Aircraft Warning Service, or
- 2 As a member of the Civil Air Patrol, or
- 3 As a member, in accordance with regulations prescribed by the Director of the Office of Civilian Defense, of the United States Citizens' Defense Corps in the protective services in civilian defense, or
- 4 As a registered trainee, taking training for such protective services, or
- 5 As an officer or member of the crew of a vessel owned or chartered by the Maritime Commission or the War Shipping Administration, or operated under charter from such commission or administration

¹ 8 Fed Reg 14158 (Oct 19, 1943)

FEDERAL AID

A state plan having been approved by the Federal Security Administrator, the federal contribution will cover (1) the entire state administrative expenses of the program, (2) the entire cost of rehabilitation of war disabled individuals and (3) one half of the cost of the rehabilitation of other disabled persons. If any state is found by the administrator to have substantially exhausted its fund for necessary expenditures in connection with its rehabilitation plan, he may until July 1, 1945 increase the federal amounts payable to the state.

REMEDIAL TREATMENT OF PHYSICAL HANDICAPS

The House Committee on Education in H Report No 426 had this to say about physical restoration of the disabled in justification of the provisions in the new law providing for such restoration:

With respect to the great inadequacy or complete lack of, necessary physical restoration under practically all programs, with the exception of New Jersey, Connecticut and Wisconsin, your committee found that under the present program anything done in this field was done without any federal contribution. To put it mildly, the states had been encouraged to retrain a person around a disability even where it would be more economical and satisfactory to eliminate the handicap itself. Federal funds are available for half the cost of the retraining approach but no federal funds are at present made available for the more obvious and satisfactory approach.

And again

Your committee considered most carefully the testimony of witnesses with respect to physical restoration, and drafted provisions which it is believed will permit the provision of such services but at the same time limit such services, both as to scope and as to recipients, so as to avoid any possibility of making the vocational rehabilitation grants available for a state health or medical program.

Physical restoration must be particularly emphasized in speedily placing large numbers in productive employment. The testimony made clear that relatively simple operations are all that are needed to make a great many people available for work. Provision of physical restoration by the states under existing law is not forbidden. It has not been provided in the past because of the limitation of funds and the feeling administratively that expenditures for such restoration were not authorized. Hence the present clarification.

The expanded program contemplates that a state plan will provide (1) corrective surgery or therapeutic treatment necessary to correct or substantially modify a physical condition which is static and constitutes a substantial handicap to employment but is of such a nature that such correction or modification should eliminate or substantially reduce such handicap within a reasonable length of time, (2) necessary hospitalization, in no case to exceed ninety days if federal contribution is to be received, (3) such prosthetic devices as are essential to obtaining or retraining employment.

If these services are furnished only to persons "found to require financial assistance with respect thereto" other than war disabled individuals or civilian employees of the government, the federal government will contribute one half of the cost.

FINANCIAL NEED OF INDIVIDUALS

The regulations issued by the Federal Security Agency so that the new law does not require a state to condition the acceptance of any individual or the rendition of any service

whatsoever under the plan on the financial need or economic status of the applicant. The state is free to establish and follow its own policies in this respect. A state may not however, impose a showing of financial need, other than with respect to maintenance on a war disabled civilian or civil employee of the United States. Furthermore, unless a state plan does impose a financial need requirement on a rehabilitant, with the exceptions noted, who is furnished corrective surgery or therapeutic treatment or hospitalization in connection therewith, the state will be required to assume the full expense with respect to such services.

FEES SCHEDULE FOR MEDICAL AND SURGICAL TREATMENT

A state plan to be approvable must provide such rules, regulations and standards with respect to expenditures on which federal grants are made available as the Administrator of the Federal Security Agency may find reasonable and necessary, including maximum schedules of fees for surgery, therapeutic treatment, hospitalization, medical examinations and for prosthetic devices.

The new regulations provide that, pending a federal determination of such maximum fees and schedules of fees, a state plan should indicate all fee schedules and all arrangements in existence with individuals, agencies or institutions, public or private, affecting the amounts of fees for such treatment and training. Such fees and costs may not, unless previously federally authorized, exceed those paid for similar services in the state by other public agencies such as workmen's compensation, public health, crippled children, public welfare and similar agencies.

FACILITIES MADE AVAILABLE BY FEDERAL GOVERNMENT

Section 5 of the law authorizes the Administrator of the Federal Security Agency to enter into agreements with two or more state vocational boards needing special facilities and services and to furnish such services and facilities on a cost basis. The administrator is authorized to establish the facilities needed.

The new regulations provide that in order to facilitate equitable and effective application of the foregoing authority, state officials should submit as soon as may be convenient comprehensive lists and evaluations of public and private facilities available to the state for rehabilitation purposes and the area feasibly served thereby, indicating fields essential to a well rounded program of vocational rehabilitation with respect to which individual plans cannot be developed by reason of the lack of remoteness or unavailability of facilities.

In addition, it is suggested that each state board should make recommendations to the federal agency as to the means and methods by which the availability and potentially utilizable facilities can be developed through arrangements with other states for the use of such facilities or conversely as to the possibilities for making facilities available to areas in neighboring states in or near to which such facilities may be located or from the use of which adjoining areas might derive substantial benefit.

ADVISORY COMMITTEES STATE AND FEDERAL

The regulations provide that a state plan should set up a representative advisory committee. It is recommended that technical committees be formed in the fields of (a) medicine and surgery, (b) education general and vocational, and (c) vocational guidance, employment and placement of individuals. It is further suggested that a general committee be established which is equally representative of management and labor and which will include among others, representatives from the workmen's compensation agency, crippled children's agency, state department of welfare or security commission, civic and service organizations interested in the development of the program, as well as representatives from professional fields. In cases involving administration by an agency for the blind, a state plan may provide for a separate advisory committee in relation to the blind.

The Administrator of the Federal Security Agency has announced the appointment of the following national Rehabilitation Advisory Council to advise the Office of Vocational Rehabilitation in connection with the expanded federal-state program.

Clair M. Andrews, president, National Rehabilitation Association, Tallahassee, Fla.

Dr. Homer Cheek, executive secretary, Commission for the Blind, Raleigh, N. C.

Dr. A. W. Dent, president, Dillard University, New Orleans.

Dr. Kendall Emerson, managing director, National Tuberculosis Association, New York.

W. I. Faulkes, chairman, State Rehabilitation Advisory Council, Madison, Wis.

Dr. M. F. Frampton, New York Institute for the Instruction of the Blind, New York.

Miss Bell Grove, executive secretary, Cleveland Association for Crippled and Disabled, Cleveland.

Stanwood I. Hanson, assistant vice president, Liberty Mutual Insurance Company, Boston.

Jay Hormel, president, George A. Hormel and Company, Austin, Minn.

F. Jay Howenstine, executive secretary, National Society for Crippled Children, Elkhart, Ohio.

Monsignor John O'Grady, secretary, National Conference of Catholic Charities, Washington, D. C.

Howard Russell, director, American Public Welfare Association, Chicago.

Col. John N. Smith, Jr., director, Institute for the Crippled and Disabled, New York.

Dr. George S. Stevenson, Council on Rehabilitation, American Psychiatric Association, New York.

Dr. George D. Stoddard, state commissioner of education, Albany, N. Y.

Miss Marjorie Taylor, first vice president, National Occupational Therapy Association, Curative Workshop, Milwaukee.

Frank G. Thompson, director, State Department of Registration and Education, Springfield, Ill.

Dr. Philip Wilson, New York Society for Relief of the Ruptured and Crippled, New York.

Miss Catherine Worthingham, president, American Association of Physiotherapy, Leland Stanford University, Palo Alto, Calif.

Miss Betty Wright, American Society for the Hard of Hearing, Washington, D. C.

SPECIAL TECHNICAL SUPERVISION, CONSULTANTS

A state plan, the federal regulations suggest, should indicate the arrangements made or that will be made for the competent technical supervision of plan operations in the following respects: medical direction, psychiatric services and training and placement services. If it is not feasible to provide full time staff officials properly qualified from the technical standpoint in these respective fields, a state plan should indicate arrangements for services of properly qualified consultants to be available in the regular course of administration.

STATE LEGISLATION

If any state was unable to comply with the conditions of the new federal law on the date of its enactment, such state may nevertheless obtain the benefits of the law until sixty days after the legislature of such state first meets in due course after such date of enactment or until the earliest effective date after such sixty days which could be given in such state to legislation passed within such sixty days to secure the benefits of the federal law, whichever is the later. In the meantime, however, a state must comply with the federal law to the extent possible.

DISTRICT OF COLUMBIA

All operations within the District of Columbia pursuant to the new law will be administered by the Division of the Federal Office of Vocational Rehabilitation known as the District of Columbia Rehabilitation Service. All applicable provisions of the new regulations including the formulation by the service and submission for approval of a plan for the District will govern the operations of the service. The service will assume responsibilities with respect to providing rehabilitation services for resident war disabled civilians and employees of the United States disabled while in the performance of duty equivalent to those of the respective states.

OFFICIAL NOTES

MEETING OF COMMITTEE ON POST-WAR MEDICAL SERVICE

The Committee on Postwar Medical Service met in Washington, D C, on October 15. There were present

Dr Roger I Lee, chairman	Dr Alan Gregg
Dr Irvin Abell	Dr James M. Mason
Dr Arthur W. Allen	Rear Admiral Dallas G. Sutton
Lieut. Commander Edward L. Bortz	Dr James A. Prullin
Dr Fred A. Collier	Dr Walter W. Palmer
Dr Warren F. Draper	Dr G. Morris Piersol
Dr Morris Fishbein	Dr Olin West

The meeting began with an extended discussion of various developments and events since the committee's first meeting on June 5 last, and the bearing such events may have on the scope and plan of the committee's services. Within the advisory function which the committee may discharge vis a vis the Board of Trustees, the following subjects were examined and discussed according to a list prepared by the chairman:

- 1 The appointment of a secretary
- 2 Problems centering around the relocation of physicians
- 3 Aspects of graduate education and specialist training refresher courses, internships, residencies and so on for men now in military service of the United States when they are returned or returning to civilian status
- 4 The problem of serving certain needs of the profession of those foreign countries whose systems of medical education and medical practice will have undergone profound strain by the end of the war
- 5 The extent to which the membership of the committee can appropriately be increased
- 6 The desirability of securing information from physicians now in military service or parallel circumstances as to their views regarding further training and education and the type of positions wanted when their war services draw to a close

The action taken may be summarized as follows:

After the appointment of a secretary, various aspects of the location or relocation of medical officers returning from the war were discussed and a subcommittee of Drs. Allen, Piersol and Gregg (chairman) was appointed to report at the next meeting. In the discussion, emphasis fell on the importance of determining the committee's position in this matter promptly and on the unquestionably complicated nature of fitting physicians to appropriate and satisfactory positions quickly and in several thousands.

A subcommittee consisting of Dr. Palmer, chairman, Dr. Collier and Dr. Blake was appointed to study and report on postwar vocational training periods—internships, residencies and training for the specialties—which affect physicians and medical students. The planning in this direction may involve advice to governmental agencies as well as educational institutions.

The placement of returned physicians in residencies will undoubtedly be at best limited, but so important is it to find the largest possible number of opportunities for young men who went into the service without residencies that the attention of

all medical schools and hospitals is called to this need. In the case of internships the resources are larger, but so will be the demand.

Of cardinal importance in supplying facts for the use of both the aforementioned committees is the collection of information from physicians in service as to what they want in point of internships, residencies, specialist training, other education, salaried positions, locations or changes of location. Dr. Abell was appointed chairman of a subcommittee with Dr. Mason and Dr. West to assist him in taking the steps necessary to secure an adequate idea of the types and number of needs, as they may be ascertained directly and in the near future, for the committee's guidance.

The committee expressed its sympathetic concern with the needs of the medical profession in the invaded countries. In view of present difficulties in securing adequate information and the present inaccessibility of the United States to most of the European doctors most in need, the committee reserved decision on this matter to a later meeting.

Because of the importance of the Veterans' Bureau Services in many phases of postwar medicine, a motion was unanimously approved to invite the director of the Veterans Bureau to designate a representative as a regular member of the committee.

In answer to the letter of inquiry and application for membership from the Association of Hospital Interns, the committee expressed itself as not prepared at the present time to enlarge its membership, especially since some physicians in military service may be added as representative of that group, in addition to Rear Admiral Sutton and General Rankin.

The meeting adjourned at 3 20 p m.

ALAN GREGG, M D, Secretary

THE A M A MARCH

Familiar strains of catchy march music have identified the American Medical Association-National Broadcasting Company network radio programs since they were first dramatized in 1935. This identification, or musical theme, as it is known in radio circles, was written for the program and copyrighted to assure exclusiveness. It has now been expanded into a march¹ and published as a piano solo.

Subject to appropriate arrangements under the copyright laws, this music can be used to identify radio programs by the medical profession locally.

The use of music in conjunction with radio programs, even when it is only an introductory and closing movement of a few bars, helps to identify the program and establish an appropriate mood. The music of the A M A March has a definite and catchy swing in march tempo, but it also expresses the appropriate dignity of the medical profession.

The writing and publication of this music is one of the many indications of the acceptance by radio of dramatized health education programs such as "Your Health," "Medicine in the News," "Doctors at Work" and "Doctors at War."

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Bills Introduced—H. Res. 328, introduced by Representative Rogers, Massachusetts, requests the President to furnish the House of Representatives with the following information: (1) the number of beds now available in all hospitals under the jurisdiction of the United States or the District of Columbia, or in private institutions under contract with the United States, and the number and type of patients in such hospitals, (2) the number of beds to be available in hospitals now under construction by the United States, together with the approximate dates on which such hospitals will be placed in service, (3) plans

for future construction of government hospitals and (4) the maximum number of war casualties which it is estimated must be hospitalized at any one time.

H. R. 3272, introduced by Representative Clegg, Massachusetts, proposes to authorize an appropriation of an amount necessary to provide loans to war service persons to enable them to complete their education. H. R. 3460, introduced by Representative Smith, Wisconsin, proposes to enact a Veterans' Training and Education Act of 1943 under which to provide vocational training and college education for veterans of the service in war.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

ALABAMA

Cancer Program Launched—A recent appropriation by the state legislature makes possible the inauguration of a state-wide program of cancer control in Alabama. For the first year \$30,000 has been set aside and for the second year \$50,000 to finance the project which will be administered by the state board of health. A cancer control committee has been named by the Medical Association of the State of Alabama to cooperate in the program. The appropriation will enable the active educational program to continue and provides the means of treating indigent patients with cancer who may apply for state aid. According to the state medical journal the program does not anticipate state owned or state operated clinics but will depend on the cooperation of individual hospitals or clinics or private physicians who can group themselves to qualify for receiving state aid patients. Each clinic recognized for such indigent patients will be given such publicity that it will be generally known as a cancer treatment center. All applications for state aid must come through the county health officer must give the details of the patient's lesion and must be accompanied by a certificate of indigence from the county department of public welfare. Arrangements will be made with cancer clinics as to the remuneration to be allowed for services rendered. The financial arrangements will be patterned after other states that have become well established in cancer control work. The state journal points out that there are only two cancer clinics in Alabama at present recognized for this work but that there are a number of groups of physicians and hospitals already treating cancer with excellent results who can be organized along these lines.

ARIZONA

Personal—Dr. Edward S. Godfrey Jr., Albany, state health commissioner of New York, was guest of honor at a dinner, September 22 given by the Maricopa County Medical Society, Phoenix.

State Society to Publish Journal—*Arizona Medicine* has been selected as the name for the new journal to be published by the Arizona State Medical Association. It will be a bimonthly publication, the first issue of which is to appear in January. Dr. Frank J. Milloy has been chosen as editor and Dr. Jesse D. Hamer, both of Phoenix, associate editor. The new journal will have an organization section of which Dr. Otto E. Utzinger, Ray, president of the state association will be editor. The *Bulletin* now published by the Arizona group will be discontinued. The decision to publish its own state journal was reached when the group managing *Southwestern Medicine* decided to discontinue it for the duration the last copy to appear in December. This publication has been the official journal for the Southwestern Medical Association, Arizona State Medical Association, El Paso County Medical Society and the New Mexico Medical Society.

CALIFORNIA

Changes in Hospital Superintendents—Dr. Burton A. Adams, medical superintendent of the San Diego County General Hospital for four years, has resigned, effective November 1. Newspapers reported—Dr. Austin U. Miller, Porterville, has been named superintendent of the Tulare County General Hospital, Tulare.

Human Plague—Plague was reported in an 11 year old boy residing on an Indian Reservation in Quartz Valley, Siskiyou County, during the week ended August 28. According to *Public Health Reports* the infection was believed to have been contracted on a hunting trip in the mountains near Fort Jones. One human case of plague was reported in Siskiyou County in November 1942 (terminating fatally on Jan. 10, 1943) and 2 fatal cases were reported in the county in 1941.

Mussel Poisoning—Four Deaths—The first cases of mussel poisoning that have occurred in the state since 1939 have appeared in Humboldt and Del Norte counties, according to *California's Health*. Twenty-two persons became ill, 4 of whom died. An annual quarantine is established on mussels along the California coast from May 1 to September 30 of each year.

The establishment of the quarantine is well known and the persons who were taken ill in this outbreak disregarded the quarantine.

Hearing Conservation Program Started—Warren H. Gardner, Ph.D., for the past three years consultant in hearing and vision for the Oregon State Board of Health, has been placed in charge of a new hearing conservation program of the state department of public health. Headquarters of Dr. Gardner, whose title is specialist in hearing conservation, will be in San Francisco. The new activity of the state department of public health was set up under recently enacted legislation providing that the department must seek out children who may have hearing handicaps. The program has been placed under the bureau of maternal and child health in order that it may be correlated to the conferences conducted by the bureau where complete physical examinations are given to children of both preschool and school ages. According to *California's Health*, Dr. Gardner has conducted similar activities in Indiana and Iowa. He is president of the American Society for the Hard of Hearing and has recently been made a lay member of the committee on conservation of hearing for the American Academy of Ophthalmology and Otolaryngology.

COLORADO

University News—Dr. James C. Magee, major general, U. S. Army, formerly surgeon general of the U. S. Army, lectured on tropical medicine before the students of the University of Colorado School of Medicine, Denver, recently. General Magee recently returned from a tour of camps in North Africa.

Club Building for Colorado Physicians in Memory of Dr. Sewall—The home of Mrs. Isabel J. Sewall, widow of Dr. Henry Sewall, Denver, may be converted into a club building, named for Dr. Sewall, for Colorado physicians and scientists, newspapers reported. Mrs. Sewall's will, filed for probate in the county court, asked that the residence at 1360 Vine Street be used as a club building "with the thought and purpose that this home, so long associated with the name of Dr. Henry Sewall, may continue to be so regarded." Mrs. Sewall left her home to Dr. Cuthbert Powell, Denver, with the request that it be used for the purpose named in the will, according to the *Denver Rocky Mountain News*.

ILLINOIS

Another Bicounty Defense Health Unit—Alexander and Pulaski counties, recently declared "defense zones for public health purposes, on September 1 combined to form the second locally directed bicounty defense zone health department in Illinois, according to the *Illinois Health Messenger*. The new full time agency, set up by the county authorities of the two counties with the war emergency aid of the Illinois Department of Public Health, is under the supervision of Dr. Donaldson F. Rawlings, with offices in Cairo. Dr. Rawlings' position as health officer of the Lawrence County Defense Zone Health Department, Lawrenceville, has been filled by Dr. Luke W. Frame, formerly health officer of Lauderdale County, Tenn. The first bicounty unit was formed by Fulton and McDonough counties of the thirty-two Illinois counties designated as "health defense counties," sixteen of which have developed full time state aided local health services for the year round scientific control of preventable diseases.

Chicago

Dr. Gellhorn Goes to Minnesota—Dr. Ernst Gellhorn, professor of physiology, University of Illinois College of Medicine, has taken over a recent appointment as professor of physiology at the University of Minnesota Medical School, Minneapolis, and head of a special unit in neurophysiology for the study of infantile paralysis that the National Foundation for Infantile Paralysis is sponsoring for Minnesota (THE JOURNAL, July 24, p. 883).

KANSAS

Personal—Dr. Warren F. Bernstorf was recently elected president of the Winfield Board of Education—Dr. George R. Dean McPherson was appointed a member of the Kansas State Board of Registration and Examination October 6 filling the unexpired term of the late Dr. Omar L. Cox, Iola—Dr. Ernest J. Beckner, Pratt, has been appointed health officer of Butler County. He succeeds Dr. Samuel N. Mallison.

Course on Medical Protozoology—On October 27 a course on medical protozoology opened at the University of Kansas Lawrence to continue to November 2 under the auspices of the University of Kansas Extension Division. The course is available for laboratory technicians in the state and

consists of study and laboratory work on malaria and its three species, *Trypanosoma* and *Leishmania* (the sleeping sickness of Africa and South America), *Endamoeba histolytica*, intestinal flagellates of man and intestinal ciliates and sporozoa. Miss Mary E. Laison, assistant professor of zoology at Kansas, is directing the course.

KENTUCKY

Society News—On October 7 Dr. Aura J. Miller spoke before the Transylvania Medical Society in Louisville on "A Common But Seldom Diagnosed Lung Disease"—Dr. John W. Moore presented "Pregnancy Complicated by Bacterial Endocarditis (case report)" before the Louisville Medico-Chirurgical Society, October 8, and Dr. Harry S. Frazier, "Medical Practice During Wartimes", both are from Louisville.

Personal—Dr. Oliver P. Miller has been appointed chief medical officer of the Veterans Administration Facility in Lexington, succeeding Dr. Letcher L. Trent, who was transferred to a veteran's hospital at Mendota, Wis.—Dr. Leon A. Beardsley, Ithaca, N. Y., has been appointed health officer of Caldwell, Lyon and Crittenden counties, effective August 24.—Dr. Ellsworth H. John, Brownsville, has been appointed in charge of the tri-county health unit of Meade, Breckinridge and Hancock counties, with offices in Hardinsburg.

LOUISIANA

Changes at Louisiana—Recent appointments to the University of Louisiana State University School of Medicine, New Orleans, include that of William L. Williams, Ph.D., New Haven, Conn., to assistant professor of anatomy. Promotions at the medical school include

Ralph A. Bullif, Ph.D., to assistant professor of anatomy
Dr. Robert H. Bayley to associate professor of medicine
Dr. Louis A. Monte to clinical associate professor of medicine
Dr. Rupert E. Arnell to professor of obstetrics and gynecology

MAINE

Naturopath Jailed for Illegal Operation—Carl E. Ahlquist, a Portland naturopath, in October started serving an eleven months jail sentence after the Maine law court had overruled exceptions filed following his conviction on an illegal operation charge at the January superior court term, newspapers reported. The law court ruled that "the record in this case discloses ample and sufficient evidence to prove beyond a reasonable doubt that the respondent, for a required fee," performed an illicit operation. At the court trial in January Ahlquist was found guilty of the charge by a traverse jury and was sentenced to serve eleven months in jail and pay a \$1,000 fine by Justice Albert Beliveau. In the trial Ahlquist was charged with an illegal operation on a 21 year old woman and county attorney Richard S. Chapman declared the operation had caused the woman to be ill, "so ill that there were grave doubts she would live."

MICHIGAN

Treatment for People with Defective Hearing—With the financial assistance of the Mott Foundation a new service has been added to the health program of Hurley Hospital, Flint, for the treatment of persons with defective hearing. The original work in the treatment of middle ear deafness with radium, particularly in children, was done by Dr. Albert C. Furstenberg, dean, University of Michigan Medical School, Ann Arbor, and his staff. The Mott Foundation has financed the purchase of additional radium for Hurley Hospital and the necessary applicators for the work. The Mott Foundation was established several years ago by Mr. Charles S. Mott, Flint, a vice president of the General Motors Corporation. It sponsors various educational projects and outdoor activities. Within the last three years the foundation has financed a tuberculosis case finding program for all senior high school students in Genesee County, the work being carried on with the photoroentgen unit at Hurley Hospital. There is also a fund for work with crippled children to supplement that provided by the state, a project which is also being carried on at Hurley Hospital.

MINNESOTA

New Officers of Northern Minnesota Group—Dr. Herbert H. Leibold, Parkers Prairie, was elected president of the Northern Minnesota Medical Association at its annual meeting in Duluth, August 29. Dr. Richard Bardon, Duluth, was named vice president and Dr. Richard N. Jones, St. Cloud, was reelected secretary-treasurer. The time and place of the 1944 meeting will be determined at a meeting of the new board early in 1944.

Hospital Planned at Mayo Clinic—Plans are under way to construct a 1,200 bed hospital to be operated in conjunction with the Mayo Clinic, Rochester, according to *Hospitals*. The proposed construction will be eighteen stories high and cost \$6,000,000. It will be built in two units, with construction work starting as soon as materials are available. Twenty operating rooms and the same number of recovery rooms will be built into the third floor. Patients' rooms will extend from the fifth to the eighteenth floor. Both operating and patients' rooms will be furnished with equipment for air sterilization by light.

Corporation Practice Illegal in Minnesota—Because a corporation cannot practice medicine or dentistry in Minnesota the Midwestern Agricultural Workers' Health Association created to provide health services to migratory agricultural workers who could not obtain the specified services from other sources, will not be able to serve migratory workers in Minnesota. The association was incorporated under the state of Indiana and was to serve all the workers in Ohio, Indiana, Iowa, Illinois, Missouri, Wisconsin, Michigan and Minnesota, the states in which these migratory workers are employed who are imported from Jamaica in accordance with an agreement with the U. S. Department of Agriculture. Dr. Franklin S. Crockett, Lafayette, Ind., was elected president of the board of seven directors, three of whom were to be physicians in good standing in their state medical societies. *Minnesota Medicine*, in reporting the situation, states that other arrangements are under consideration to care for these workers.

NEW JERSEY

Society Announces Season's Programs—The Cumberland County Medical Society opened its 1943 season October 12 with a talk in Bridgeton by Dr. Harry E. Bacon, Philadelphia, on "Diagnosis and Treatment of the More Common Anorectal Affections." Dr. Thaddeus L. Montgomery, Philadelphia, spoke October 21, on "The Diagnosis and General Management of Ovarian Neoplasms." Subsequent meetings will be addressed by

Dr. John R. Beardsley, San Diego, What Life Teaches a Physician, November 9
Dr. Abraham I. Rubenstein, Philadelphia, Diabetes Mellitus, Its Treatment December 14
Dr. Robert A. Matthews, Philadelphia, Common Psychosomatic Problems Encountered in General Practice Feb. 8, 1944
Dr. William Harvey Perkins, Philadelphia, Medicine in Applied Science, April 11
Dr. Temple S. Fay, Philadelphia, Neurological Lesions in Children June 13

John Scott Medal Awarded for Work on Swine Influenza—Dr. Richard E. Shope, Princeton, N. J., a member of the Rockefeller Institute for Medical Research, has been awarded the John Scott Medal and "pennum" of \$1,000 by the city of Philadelphia through its board of directors of City Trusts, for his "discovery of the complex etiology of swine influenza." Dr. Shope graduated at the State University of Iowa College of Medicine, Iowa City, in 1924. He is 41 years of age. Mr. John Scott, chemist of Edinburgh in 1816, bequeathed to the city of Philadelphia the sum of \$4,000, the income of which was to be "laid out in premiums to be distributed among ingenious men and women who made useful inventions." Reports concerning the award indicate that little is known concerning the donor or why he selected Philadelphia. The fund has been managed in turn by the city councils, the Franklin Institute and finally by the directors of City Trusts. It has grown to more than \$100,000.

NEW YORK

Lectures on the Biology of Cancer—A course of practical teaching lectures on the 'Biology of Cancer' was to begin during October for biology teachers in public and private schools and colleges throughout Westchester County. The course will consist of four to six lectures by Clarence R. Hatter, Ph.D., assistant biologist at Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York, under the auspices of the research council of the Westchester Cancer Committee.

Meeting on Tumors—There are now 179 cancer patients on the ten year survival list of Rochester hospitals according to a report presented by the executive secretary of the New York State Committee of the American Society for the Control of Cancer at a meeting in Rochester October 5. Seventy one of the new five year survivals were reported bringing the total of five year survivals up to 673. A scientific program was conducted by Dr. Andrew H. Dowdy, associate professor of pathology, University of Rochester School of Medicine and Dentistry, director of the Tumor Clinic of the Strong Memorial Hospital where the meeting was held. Dr. Karl M. Wilk, a professor of obstetrics and gynecology, University of Portland, was

of Medicine and Dentistry, reported 5 cases of chorionepithelioma seen in the gynecologic service since the opening of the hospital in 1926, 2 of which have reached the five year survival point. Dr Clyde A. Hartly, associate professor of otorhinolaryngology and bronchoscopes, and Dr Dowdy presented 8 patients who had been treated with laryngofissure, laryngectomy and irradiation for carcinoma of the larynx. Dr John M. Swan, Rochester is executive secretary of the New York State Committee.

New York City

Cassius Watson Retires as Medical Director of American T and T—Dr Cassius H. Watson for twenty eight years medical director of the American Telephone and Telegraph Company retired on October 1. He has been succeeded by Dr Melville H. Manson formerly medical director of the Bell Telephone Laboratories and since 1942 medical director of the New York Telephone Company.

Hospital Needs Interns—The Hospital for Joint Diseases announces sixteen places available on its general rotating service for nine months internship. One half of the number appointed may be permitted to continue for another nine months as junior residents, and thereafter one half of the number of junior residents may be continued for another nine months as senior residents. Three interns will begin on April 1, 1944, four on July 1 and four on October 1. Five interns will begin on Jan 1, 1945. The hospital provides maintenance, uniforms and a stipend of \$15 a month. Applications should be addressed to the director, Hospital for Joint Diseases, 1919 Madison Avenue, New York 35.

Salvage Potential Manpower Among Tuberculous for War Production—The New York Tuberculosis and Health Association has expanded its rehabilitation service for the guidance of recovered tuberculosis patients by appointing personnel to project the program, which has for one of its objectives the salvage of potential manpower among the tuberculous for war production. The program includes guidance and counsel to the patient in order that he may find a job consistent with his ability to work and the promotional aspect of rehabilitation. The objective of the latter is to educate medical lay and employer groups regarding the employment possibilities of former tuberculous patients, the establishment of educational facilities for patients still in hospitals and guidance to hospital personnel in planning or expanding such educational facilities. Bernard S. Coleman, S.B., secretary of the tuberculosis committee of the association, is directing the program.

American-Soviet Scientific Meeting—The National Council of American-Soviet Friendship will sponsor a meeting at the Hotel New Yorker and Madison Square Garden November 6-8. The first session Saturday will be on "Planning a Postwar Reconstruction in the U.S.A. and the U.S.S.R." On Sunday panels will be held on "Soviet Science and Technology" and on "Public Health and Wartime Medicine in the U.S.S.R.," the latter panel to be held under the auspices of the American-Soviet Medical Society. The congress sponsored by leading scientists throughout the country, has as its honorary chairmen Dr. Walter B. Cannon, Cambridge Mass., Ernest O. Lawrence, Sc.D., Berkeley Calif., and Gilbert N. Lewis, Ph.D., dean of the College of Chemistry at the University of California, Berkeley. Among the speakers will be:

Leshie C. Dunn, Sc.D., Russian Research in the Biological Sciences, C.T.A. Winslow, Dr. P.H., New Haven Conn., Public Health in the Soviet Union.

Dr. Vladimir V. Lebedenko, Russian Red Cross representative in the United States, Russian Advances in Military Medicine.

Harold C. Urey, Sc.D., has accepted the chairmanship of the panel on Soviet Science and Technology.

Two Cents a Day Plan Offered by Hospital Service—In an effort to bring additional medical care and hospitalization to the lower income group, the Associated Hospital Service of New York plans to introduce a two cents a day plan to supplement the three cents a day plan. Ward accommodations instead of the semiprivate rooms available under the existing program, will account for the difference in price according to the New York Times. Ninety-two hospitals had agreed to give this new service on October 15 but, it was stated, between forty and fifty more were needed before the program could go into operation. Rates to the public will be about 20 per cent lower than those now in effect for an individual; they will be about 56 cents a month and for a family \$1.50. Under the new contract, which has been cleared by the state insurance department, subscribers will be entitled to all ward services including room and board, use of the operating room, x-ray facilities, medication, drugs and dressings. As in the three cents a day plan there will be a twenty-one day benefit period. If necessary, the subscriber will obtain a 50 per cent discount for an additional ninety day hospital stay. To receive these accommoda-

tions the subscriber must be eligible for admission to the ward under the rules of the individual hospitals. The patients who cannot be admitted to the ward will be entitled to the use of a semiprivate room on payment of a small fee to the hospital, the Times reported. Maternity benefits will be provided only under the family contract. These will be limited to \$4 a day for ten days in normal cases. Should complications develop in maternity cases the subscriber will receive full benefits.

Advances in Medicine—A series of lectures on the Advances in Medicine will open at Mount Sinai Hospital, November 24, with members of the staff participating. The program is as follows:

Dr. Robert T. Israel, Recent Advances in Endocrine Therapy, November 24.

Dr. Mary I. Susman, Recent Advances in the Diagnosis of Congenital Heart Disease, December 8.

Dr. Gregory Schwartzman, Recent Advances in Bacteriology and Virus Research with Special Reference to Electron Microscopy, December 22.

Dr. Israel S. Wechsler, Recent Advances in Neuropsychiatry with Special Reference to the Electroencephalogram and the Shock Treatment of Psychoses, January 5.

Dr. John H. Garlock, Recent Advances in the Surgical Treatment of Diseases of the Esophagus, January 19.

Dr. Burrill B. Crohn, Recent Advances in Gastritis and Ileitis, February 2.

Dr. Asher Winkelstein, Recent Advances in Ulcerative Colitis, February 2.

Dr. Ira Cohen, Recent Advances in the Diagnosis and Treatment of Intracranial Lesions, February 16.

Dr. Ralph Colp, Recent Advances in the Surgical Treatment of Gastric Duodenal and Jejunal Ulceration, March 1.

Dr. Arthur M. Fishberg, Recent Advances in Hypertension, March 15.

Dr. Reuben Ottenberg, Recent Advances in Chemotherapy, March 29.

Dr. Louis J. Soffer, Recent Advances in the Physiology of the Thyroid and Adrenal, April 5.

Dr. Paul Klempner, Recent Advances in Cellular Pathology, April 19.

Dr. Nathan Rosenthal, Recent Advances in the Study of the Hemolytic Anemias, April 26.

Dr. Harold Neuhof, Recent Advances in the Problem of Pulmonary Embolization, May 3.

PENNSYLVANIA

Physicians Honored—Four physicians were presented with testimonial certificates indicating the completion of fifty years in practice of medicine at a meeting of the Second Council District of the State Medical Society, Reading, September 8. The physicians are Drs. George C. Webster, Chester; Harvey F. Scholl, Prospect Park; Charles H. Schoff, Media; and George F. Seiberling, Allentown.

Child Care Centers—On August 1 six child care centers had been opened in Pennsylvania, one each in Darby, Erie, Williamsport, Rankin, York and Pittsburgh. Supported by federal funds, these centers are designed to provide certain hours of care for children whose ages range from 2 to 14. The centers provide care to children of parents only during "employment rendering service to the community or the nation." Other centers are being developed throughout the state.

State Assumes Control of Scranton Hospital—The state of Pennsylvania will direct the Hillside Home and Hospital for Mental Diseases, Clarks Summit, as a state institution in accordance with the recent transfer of control from the Lackawanna County Institution District to the commonwealth newspapers report. The transfer was unsuccessfully opposed by the Lackawanna County commissioners. Governor Edward Martin has appointed new trustees to control the institution and Dr. Evelyn T. Davies, Old Forge, former state representative, has been named acting superintendent.

Philadelphia

Annual Alpha Omega Alpha Lecture—Dr. Russell L. F. Cecil, New York, will present the annual lecture of the Jefferson Chapter of Alpha Omega Alpha at the Jefferson Medical College, November 11, on "Rheumatoid Arthritis."

Voluntary Contributions Finance Bulletin for Service Men—Voluntary contributions from individuals, physicians and friends of the University of Pennsylvania Hospital are financing a weekly bulletin mailed each week to former staff members of the hospital serving in the armed services. The bulletin has grown from an initial three issue release to four hundred weekly copies first published in June 1942 running on an average of four mimeographed pages. Originally Dr. Bernard I. Comroe and his wife financed the endeavor but such interest has attached itself to the little paper that others seek to maintain at least one issue. Credit is given to the contributor in each issue. The bulletin contains news concerning the University of Pennsylvania School of Medicine and Hospital including results of scientific work and personal news of men at home and in the service when released by censorship. Dr. Comroe, senior ward physician at the hospital, associate in medicine at the medical school and chief of the medical division of the student health service, prepares the material with the assistance of all voluntary contributors.

SOUTH CAROLINA

Personal—Dr. Dargan Strother Pope, Columbia, has been appointed a member of the board of trustees of the Medical College of the State of South Carolina, Charleston, to fill the vacancy created by the death of Dr. Thomas H. Pope, Newberry.

Physician Sentenced on Mail Fraud Charge—Dr. Benjamin I. Siegel, Rock Hill, was sentenced to three years in federal prison in the closing case of federal court in Rock Hill, September 8, on a charge of using the mails to defraud, according to the *Charlotte Observer*. Dr. Siegel is alleged to have charged the beneficial fund of the Rock Hill Printing and Finishing Company with services to employees. He mailed such bills and received payment also through the mails, the government charged. The physician had first entered a plea of not guilty but later changed his plea to guilty, it was stated.

TEXAS

New Health Unit—A new health department has been set up in Galveston County with headquarters in LaMarque. Dr. Edward M. Baines, formerly of Tampa, Fla., is the new director of health.

State Psychopathic Hospital Closed Temporarily—The Galveston State Psychopathic Hospital has been closed temporarily for repairs. Dr. David Wade, acting superintendent, has been assigned to Austin in the office of the state board of control to serve as clinical director of state hospitals.

Motion Picture Lending Library Established—The State Medical Association of Texas has established a motion picture lending library. There will be a charge to cover the cost of transportation and handling, and borrowers will be required to pay the costs of damages to films while in their possession. The library now has a number of films which have been lent out by a number of firms for relending purposes.

UTAH

Dr. Wintrobe Named Professor of Internal Medicine—Dr. Maxwell Myer Wintrobe, formerly associate professor at the Johns Hopkins University School of Medicine, Baltimore, has been appointed professor and head of the department of internal medicine, University of Utah School of Medicine, Salt Lake City.

VIRGINIA

Portrait of Dr. Leigh—A portrait of the late Dr. Southgate Leigh, executed by W. S. Harney, was unveiled on June 10 in the staff conference room of the Leigh Memorial Hospital, Norfolk. The portrait was the gift of the Sarah Leigh Nurses' Association. Dr. Leigh, who died on March 5, 1936, founded the hospital in 1903.

Graduate Course in Otolaryngology—The eighteenth annual spring graduate course on otolaryngology and ophthalmology will be given at the Gill Memorial Eye, Ear and Throat Hospital, Roanoke, for a week beginning on April 4. The courses are available only to physicians specializing exclusively with the eye, ear, nose and throat.

GENERAL

Association for Research in Nervous and Mental Disease—"Trauma of the Central Nervous System" will be the theme of the annual meeting of the Association for Research in Nervous and Mental Disease at the Waldorf Astoria Hotel, New York, December 17-18. Dr. Jefferson Browder, Brooklyn, is president of the association and Dr. Thomas E. Bamford Jr., 115 East 82d Street, New York 28, secretary-treasurer.

Ear and Throat Meeting—The American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery will hold its first annual meeting in New York on November 12 under the presidency of Dr. Romeo A. Luongo. November 12 under the presidency of Dr. Romeo A. Luongo, Philadelphia. A clinic and business meeting will be held at the Manhattan General Hospital and a scientific meeting in the New York Academy of Medicine. The speakers at the latter will include:

Dr. Samuel Fomon, New York, The Role of Plastic Surgery in the Field of Otolaryngology.
Col. Samuel J. Kopetzky, M. C. A. U. S., subject not announced.
Dr. Alfred Schattner, New York, Report of Isograph Transplants in Identical Twins.
Dr. Arthur W. Proetz, St. Louis, Physiology of the Nose.

College of Chest Physicians—The American College of Chest Physicians, Southern Chapter, will meet at the Hotel Gibson, Cincinnati, November 16-18, during the session of the Southern Medical Association. Speakers at a luncheon session sponsored by the Ohio State chapter of the college of chest

physicians will be Drs. William A. Hudson and David S. Brachman, Detroit, on "A Study of Rejection for Thoracic Abnormalities." A dinner meeting will be addressed by Dr. J. Rodriguez Pastor, San Juan, P. R., on "The Tuberculosis Problem in Puerto Rico." Other speakers will include:

Dr. Arnold S. Anderson, St. Petersburg, Fla., Chest Diseases in the Aged.
Dr. Jesse D. Riley, State Sanatorium, Ark., The Relative Importance of the Anatomic and Physiologic Concept in Tuberculosis.
Lieut. Col. Carl W. Tempel, M. C., U. S. Army, New Growths of the Chest.
Col. Arden Freer, M. C., U. S. Army, The Occurrence of Pulmonary Tuberculosis in Supposedly Screened Selectees.
Lieut. Comdr. Derm. F. Smiley (MC), U. S. Naval Reserve, Tuberculosis as a Navy Problem.
Dr. Chester A. Stewart, New Orleans, Tuberculosis Among Children and Young Adults.
Dr. Everts A. Graham, St. Louis, The Indications for Total Pneumectomy.
Drs. Paul H. Holinger and Ralph G. Rigby, Chicago, Bronchoscopic Kodachrome Motion Pictures of Tracheal and Bronchial Tuberculosis.
Dr. Richard M. Davison, Chicago, Lung Resection in Chronic Pulmonary Diseases.

Medical Panel Created by Automotive Council—A medical panel has been created by the Automotive Council for War Production to make available to all automotive companies the experience and knowledge developed in the medical departments of the leading companies, to the end that the whole industry may have the benefit of information available on general or specific questions of industrial health. At its organization meeting, August 25, Dr. John J. Pendergast Jr., medical director, Chrysler Corporation, was elected chairman. Members of the panel, all heads of the medical staffs of their companies, are Dr. Archibald W. George, Packard Motor Car Company (Joseph L. Zemens, alternate), Frank J. Jarzynski, Bohm Aluminum & Brass Manufacturing Corporation, William T. Krebs, Hudson Motor Car Company, Harley L. Krieger, Ford Motor Company (Howard P. Staub, alternate), Clarence H. Kuhlmann, Cleveland Graphite Bronze Company, Clarence D. Selby, General Motors Corporation, and Dr. Pendergast, Chrysler Corporation (Stuart F. Meek, alternate), all of Detroit. Harlan V. Hadley, associate manager of the Council's Manpower Division, is secretary of the group. At present consisting of seven members, the panel is to be expanded to twelve members, with the panel itself nominating and electing new members. The panel has entire freedom to limit or expand its activities, subject only to the provision that such activities must be in the national interest of "expediting the output of armaments for the fighting forces." It is planned to hold four meetings of the panel annually in the hospital offices of the members to discuss and act on medical questions of industry-wide import. It is also planned to maintain the complete anonymity of the source of inquiries and the source of replies to such inquiries. All questions will be addressed to the secretary, Harlan V. Hadley, who will forward them with all signs of identification removed to all members of the panel. Members in turn submit their replies to the secretary, who forwards them, again with all signs of identity removed, on instruction from the chairman, to the member of the panel designated to write a composite report. The composite report is then supplied to the source of the question over the secretary's name and with the name of the doctor who wrote it withheld. The policy will be to answer inquiries on a purely scientific basis rather than from a standpoint of the individual practice of the doctor's company. Another policy will be that the chairman may answer inquiries as to medical standards by citing the standards created by recognized medical groups, when available, with or without modification as each situation requires. This modification principle is shown in the government's standard for the employment of pregnant women. Where the government suggests a minimum of six weeks' leave for the woman before delivery and a minimum of two months' leave after delivery, the panel feels that she should leave her employment on or about the third or fourth month of gestation, depending on her specific condition, and not return until she is three months post partum. Other questions before the panel are the employment of partially disabled war veterans or other physically handicapped persons; dermatitis, the general use of vitamin pills; the relief of overextension resulting from fatigue; preemployment physical examinations and periodic continuing examination of food handlers.

Report of Rheumatic Fever Conference—On October 5 and 6 and 7 the Children's Bureau of the U. S. Department of Labor held a national conference in Washington, D. C., on rheumatic fever. Since 1939 a portion of the federal health appropriated annually for crippled children's services has been used for the development of state services for children with rheumatic fever and heart disease. Fourteen states have been

such programs in operation and several additional states have completed plans for the development of these services. Attending the conference were representatives from state agencies, members of the Children's Bureau Advisory Committee, experts in the field of clinical investigation pertaining to the problem of rheumatic fever, and representatives of numerous lay and professional organizations concerned with the health and welfare of the rheumatic child. At the opening session of the conference Col Leonard G Rowntree, M R C, chief, Medical Division Selective Service System, pointed out that rheumatic heart disease is responsible for thousands of rejections from the armed forces. Among 13,000,000 men examined over 230,000 were classified as 4 F because of cardiovascular disease. Dr Rowntree estimated on the basis studies made by the National Research Council that nearly half of these cardiovascular defects were caused by rheumatic fever. Brig Gen Hugh J Morgan, A U S, medical consultant, Surgeon General's Office reviewed the current experience in the Army in dealing with the problem of rheumatic fever, indicating that the problem is essentially the same in the Army as in the civilian population. He urged that civilian health authorities follow the lead of the Army in taking vigorous steps to combat this disease. Lieut Comdr Alvin F Coburn (MC), U S Naval Reserve stated that conditions in many training camps are conducive to the development of rheumatic fever.

The prophylactic use of the sulfonamides in the prevention of recurrent attacks of streptococcal infections in rheumatic patients was considered at a round table discussion. Participating in the discussion were Dr Homer F Swift New York, Commander Coburn, Dr Ann G Kuttner Boston, Dr Arild E Hansen Minneapolis, Dr Katharine G Dodge New York, Major William H Button M C A U S, Dr Caroline C B Thomas Baltimore and Dr Caroline A Chandler, Washington. There was general agreement among the discussers that the sulfonamides have been proved to be effective in the prevention of recurrent attacks of rheumatic fever. Warning was given against the indiscriminate use of these drugs without close medical supervision. The use of the drugs as a prophylactic measure for rheumatic patients should be considered only as an adjunct to a general regimen designed to provide adequate health supervision of the rheumatic child. At other sessions of the conference emphasis was placed on the importance of early diagnosis during the initial attack of the disease, referral of patients to special diagnostic clinics, examination of siblings of rheumatic children, provisions for institutional care during the period of active infection, educational and recreational activities for children confined to bed for long periods of time, special educational services for children with heart disease and coordination of community facilities and services for the care and management of the rheumatic child. Those attending the conference agreed that rheumatic fever represents an important public health problem in the United States but that facilities and services have not been developed to the point where the needs of children afflicted with this disease are being adequately met. Many members of the conference pointed to the need for further opportunities for local physicians to become more fully acquainted with the disease and with the methods for the care and management of the rheumatic child. It was apparent that the problems of children afflicted with rheumatic fever cannot be met by the services of any single individual or agency for the close cooperation of physicians, nurses, social workers, educators and others engaged in related fields. Dr Thomas Duckett Jones, Boston, in summing up the conference at the closing session called attention to the progress that had been made in many states during the past three years in the care of the rheumatic child through the development of the state programs and pointed to the need for the extension of existing programs and for the development of similar services in other states.

LATIN AMERICA

Cancer Congress—The Primer Congreso Mexicano de Cancer and Segunda Semana Medica de Occidente will be held in Guadalajara, Jalisco, Mexico, during the first week of November. Among the invited speakers are Dr Charles W Mayo, Rochester, Capt Waltman Walters (MC), U S Naval Reserve, Lieut Col James T Priestley, M C A U S, Dr Howard K Gray, Rochester, Dr Angel H Roffo, Buenos Aires, Drs Luis Paríñas and Juan Llambes, Cuba, Dr Jose Gomez Marquez, Honduras, Dr Robert Gutierrez, New York, Dr Ramon Castroviejo, New York, Dr Charles Pierre L Mathé, San Francisco, Dr Arthur Steindler, Iowa City, Dr Joseph M Hill, Dr Alfred I Folsom, Dr Charles L Martin, Sol Haberman, Ph D, Dr John D Singleton, Dr Howard I

Scott, Dr John V Goode, all of Dallas, Texas, Dr Juan Carlos Oreggia, Montevideo, Uruguay, Spencer R Atkinson, D D S, Pasadena, Calif, Ben Robinson, D D S, Baltimore, Dr Julio Fazzio Calmet, Montevideo, Dr Ricerio V Canzani, Buenos Aires, Dr Melvin S Henderson, Rochester, Dr Alejandro Wallace, Los Angeles, Dr Rudolph Matas, New Orleans, Dr Manuel M Garcia, New Orleans, Dr Enrique J Cervantes, New York, Dr Alton Ochsner, New Orleans, Dr Oscar Mercier, Montreal, Canada, Dr Verne C Hunt, Los Angeles, and Carl Voegtlin, Ph D, Washington, D C. Dr Ochsner will represent the American Medical Association at the congress.

Government Services

Dr Foard Placed in Charge of Western Public Health District

Dr Fred T Foard, surgeon, U S Public Health Service, has been assigned as medical director for the Western district of the public health service, which includes the states of Idaho, Utah, New Mexico, Colorado and Texas, with central headquarters in Denver.

Civilian Health Good, Says Report

Statistics of the U S Public Health Service show that the lowest death rate on record, 10.3 per thousand, was recorded in 1942, according to a report released by the Office of War Information. The birth rate was 207 in 1942 as compared with 187 per thousand in 1941. The maternal mortality rate dropped for the thirteenth consecutive year to about three deaths per thousand live births in 1942. Infant mortality also continued to drop. For the first six months of 1943, however, statistics indicate slightly less favorable conditions as reflected by communicable disease reports and by estimated death rates. With the exception of meningococcal meningitis (cerebrospinal fever), poliomyelitis and the dysenteries, the incidence of communicable diseases reported to the public health service during the first half of 1943 is below or approximately the same as that for the corresponding period of 1942. Cerebrospinal meningitis, which began to increase during 1942 and developed into incipient epidemic proportions toward the end of the year, has remained at a high level so far this year in spite of a seasonal decline. Up to the week ended August 14 a total of 13,368 cases had been reported. This is a larger number of cases than has been reported for any entire year since 1914, when collection of these reports was begun. The largest number of cases for any year for that period was 10,551, reported in 1929. The incidence of poliomyelitis is above that of any year since 1934. The total number of cases this year as of August 21 is 4,059, which compares with 1,505 for the same period last year and a five year median of 2,072 cases. In the week ended August 21 the last for which complete figures were available, the total was 747 cases, an increase of 201 cases over the report for the previous week. Chief centers of infantile paralysis are California, Kansas, Illinois and Texas, with cases also in Oklahoma, New York and Connecticut. There has been an increase of dysentery during the first half of the current year. About twice as many cases had been reported up to July 24 as were reported for the same period last year. This increase is probably due in part to the lack of sanitary precautions in eating establishments and carelessness among food handlers. Preliminary figures indicate a low rate in 1943 for typhoid. Up to July 24 only 2,424 cases had been reported in the United States as compared with 3,444 for the same period last year. While preliminary mortality figures through May of this year indicate a slightly less favorable death rate than last year, no significant increase has been recorded. The provisional annual death rate for the first five months of 1943 was 11.2 per thousand of population or 0.31 higher than the rate for the same period in 1942. The death rate for the entire year 1942 was only 10.3 per thousand of population, the lowest on record. The increase in the rate during 1943 apparently is due principally to the excess in death from cardiovascular-renal diseases, although increases in the deaths from some of the childhood diseases and from the cerebrospinal fever have probably also been factors, although less important numerically. According to the report, it is interesting to note that there has been no indication of increased mortality from respiratory tuberculosis in this country since the beginning of the war. In fact the death rate from this cause has been lower than in 1939 and 1940.

Sept 10, 1943

British Medical Students Association

Formation of the British Medical Students Association means that the voice of the medical student is heard for the first time in medical affairs. At first the movement was supported by only a small group of students, but it grew quickly, and within a year the association was requested by the medical planning commission of the British Medical Association to submit a memorandum on medical education. It now has a membership of over eight thousand, almost all the medical schools and teaching hospitals in the British Isles have joined. A congress of students, the first of its kind, was held in December and was attended by five hundred students from medical schools all over the country. A memorandum on medical education, based on evidence submitted by fifteen schools, was drawn up. Among its recommendations were the following: 1. Medical students should be drawn from all sections of the community without reference to financial means or sex. 2. They should have the opportunity of working within a university and not in isolated medical schools, to prevent too early dissociation from other students. 3. Newly qualified doctors should be compelled to serve a period of hospital appointment before license to practice is granted.

Another important memorandum, on student health, has been drawn up by the association. Various schemes have been tried in British universities, but none have proved satisfactory. All students, and particularly medical students, tend to live in unhealthful surroundings. The extension of university hostels and approved lodgings is regarded as the first step in improvement. Routine x-ray examination of the chest is also recommended. Since health is a problem that concerns all students, the British Medical Students Association is cooperating in the formation of this program with the National Union of Students and the British Dental Students Association. A course of eight lectures by eminent authorities on various aspects of the war has been arranged in London.

At nearly all the medical schools meetings have been held to discuss the Beveridge scheme, which on the whole is supported, though there is wide disagreement as to details. A resolution urging the government to implement the Beveridge principles without delay was carried by 34 votes to 3 at a committee meeting.

The Army Blood Transfusion Service

The Army Blood Transfusion Service has a panel of 320,000 donors. Of this number between 3,000 and 4,000 have made donations each week for some time. This service operates in an area covering practically the whole of the south of England. Major campaigns to enroll volunteers are conducted six times a year, but minor campaigns are in continuous operation in factories, villages and small towns in a definite cycle of visits. Donations are taken by fifteen mobile teams, each having a medical officer. At headquarters the blood group of each donor is ascertained and recorded. The blood of group O, from the "universal donor," is pooled and used to make fluid plasma, of which 58,932 pints have already been made for military use at home or overseas in temperate climates. For tropical and subtropical countries dried plasma with distilled water for reconstitution is supplied. Whole blood is exported to any theater of war within air distance from England, and blood banks are maintained in important civil and air force centers.

Large insulated boxes with ice inserts keep the blood at 4 C for eight hours. Overseas it is kept in cool mobile refrigerators and distributed to field transfusion units from the base unit. If whole blood remains unused after three or four weeks it is converted into plasma.

All transfusion fluids, including crystalloid solutions, are accompanied by administration apparatus in sterilized tins ready for immediate use. Sets for blood taking are also issued with supplies of dried serum for blood grouping. Special boxes of equipment are issued for the use of military hospitals, field ambulances, troop ships and air borne medical units, to which they are dropped by parachute.

The technical staff of the Army Blood Transfusion Service is under the direction of L. E. H. Whitby. It is drawn almost entirely from the laboratory staff of the Royal College of Surgeons and the Middlesex Hospital. It trains special transfusion units for service overseas and instructs all ranks of the Army Medical Corps in resuscitation work. The British army differs from all others in having a distinct transfusion service with its own source of supply and specially trained mobile resuscitation teams. In every theater of war there is a base transfusion unit, which, linked with the home service, is able to exploit local resources and thus supplement the supplies obtained from home.

New Zealand Immigration Admission of European War Orphans

In reply to the suggestion that war orphans should be received in New Zealand, Prime Minister Fraser replied that there could be no argument about the need for more population there. The government's first concern was the rehabilitation of the men fighting overseas, he indicated, but that did not preclude attention to immigration. New Zealand could take her share in helping the homeless children of the world—the government had already discussed with the Polish consul general the question of taking Polish children. Immigration questions would also be taken up with British authorities, the prime minister stated. Many British soldiers in North Africa have indicated their intention to go to New Zealand after the war, and New Zealand wishes as far as possible to keep the country British.

American Psychiatrists Entertained

Psychiatrists of the United States and Canadian forces in this country were entertained by the London County Council at Sutton Emergency Hospital. Short papers were read on Rehabilitation of the Neurotic (Dr. Minski), Psychopathic Personalities (Colonel Petrie), Recognition of the Neurotic in the Services (Dr. Slater) and Psychic Treatment in Psychiatry (Dr. Sargant). A demonstration on the electroencephalogram was given by Dr. Hill, a demonstration of electroconvulsive therapy by Dr. Sands, and visits were made to the occupational workshops. Colonel Thompson and Colonel Van Nostrand returned thanks on behalf of the United States and Canadian psychiatrists.

Writing on Pigmented Skins

When a skin pencil is used on African natives—for instance to note the administration of morphine—the writing is almost invisible. The same applies to the darker race of India. The Army Medical Department Bulletin reports that an officer in West Africa has overcome the difficulty by means of a thick emulsion prepared from talcum and any white powder, such as zinc oxide, mixed in hot water. The emulsion can be conveniently kept in a half ounce bottle from which it can be applied by means of a small pointed stick from behind the ear.

The Work of the American Red Cross in Britain

Mr Norman H Davis, chairman of the American Red Cross, who has come here to confer with Mr Harvey Gibson, American Red Cross commissioner in this country and with service leaders on future plans to meet conditions when the United States forces move into other areas has paid a tribute to the facilities provided for the American forces by various clubs and field and hospital organizations. American Red Cross activities cover operations in the Southwest Pacific, India, North Africa, Iceland and Alaska and will follow as quickly as possible in any new theater of war. In this war Red Cross activities have developed somewhat along new lines, particularly in club and welfare work. In Britain eighty American clubs are already open and seventy others are being formed. They include service clubs which provide the equivalent of homes to Americans on leave in our cities and towns. Other clubs offer all these facilities except sleeping rooms and meals.

Another type of club is the 'clubmobile,' or club on wheels, made from converted omnibuses. It carries American newspapers and magazines, writing materials, American doughnuts, coffee, cigarettes and chewing gum to men on duty in isolated camps and air bases. Each clubmobile is staffed by three American girls and gives performances of the latest phonograph records from loud speakers on the roof. Each is convertible into an ambulance to carry 10 stretcher cases.

To most American army hospitals are assigned welfare services to build up and sustain the morale of patients by providing wholesome relaxation and instruction in hobbies, arts and crafts. As to the Red Cross blood transfusion work, the surgeon general of the United States Army, who was in the Tunis campaign, told Mr Davis that as a result of the use of dried blood plasma the mortality of casualties had been reduced from 15 to 2.5 per cent. About 15,000 people are working for the American Red Cross in Britain, half of these are volunteers, and the large majority are British.

Ophthalmologic Research at Oxford

The provision and equipment of laboratories, lecture rooms, a library and a museum for ophthalmic research at Oxford University is part of an ambitious scheme to be carried out in connection with the rebuilding of the Oxford Eye Hospital, which will be undertaken at the end of the war. Salaries will be provided for full time and part time research workers, teachers and technicians. The costs of research looking toward the prevention of blindness, improved treatment of eye disease and promotion of a higher standard of visual function throughout the country will be defrayed. An important objective for the proposed department is the discovery of the safest antibacterial drugs for ophthalmic use. The extreme delicacy of the eye is the governing consideration, as all the ordinary antiseptics are poisons and further investigation will need contributions not only from ophthalmologic but from bacteriologic, mycologic and chemical sources. The most promising substance found so far is penicillin, knowledge of which is derived largely from work done in an Oxford laboratory. Statistics show that the risk of failure of vision falls increasingly on those in middle life. In 1941 out of a total blind population of 74,000 in England and Wales 63,000 were persons over the age of 40 years. The cost of the proposed scheme is estimated at \$1,000,000 for which an appeal is being made.

Library Difficulties After the War

In a letter to the *Lancet* Mr C. C. Barnard, librarian of the London School of Hygiene and Tropical Medicine states that after this war, even more than after the last, libraries will be faced with the problem of filling gaps in their sets of periodicals not only because of their inability to obtain journals from enemy and enemy occupied countries during the war but also because of losses at sea and destruction by air raids over this

country. To prevent an unseemly squabble by libraries for volumes limited in supply, he advocates decisions on a national scale by an impartial body on the allotment of volumes. This should form part of a much larger scheme whereby the present holdings of learned periodicals would be surveyed and the needs of research in the various centers of learning assessed, regard being paid to specialization in various institutions. Interchanges of stock could be arranged to insure complete sets in libraries where they are most needed. The obvious body to undertake this program is the Library Association.

Before the war two such schemes were being prepared—in the fields of German studies and of medicine. Only when this work has been completed will it be possible to compile a satisfactory union catalogue of periodicals in British libraries, which is much needed to supersede the present incomplete World List of Scientific Periodicals.

The Royal Society of Medicine in Wartime

Notwithstanding the war, the work of the Royal Society of Medicine goes on unimpaired though paper control has, as in the case of all periodicals, reduced the size of the printed proceedings and prevented the publication in them of important papers. Some, however, have appeared in the medical journals. In normal times these papers would have appeared both in the proceedings and in the journals. The membership of the society has reached the highest level ever attained, just over six thousand, and shows an increase of 50 per cent in the last fifteen years. The meetings of the society in the past year have been larger in number and better attended than ever. This is accounted for by the special interest in the topics of war medicine discussed and the large number of guests from the dominion and allied forces, to whom hospitality has been extended. By their contributions the discussions have been greatly enriched, especially by medical officers of the American and Canadian forces. Two distinguished physicians from the United States—Dr Thomas Parran and Dr Hugh Young—and Prof T. A. Jurasz of Poland have been elected honorary fellows. Interallied conferences on military medicine have been arranged for the benefit of the fighting forces. For obvious reasons the discussions will take place in private. Committees of the society are dealing with the subject of interned medical aliens, education in otorhinolaryngology and in collaboration with the Royal Medico-Psychological Society, with the future of psychiatry in all its branches.

Marriages

WILLIAM HAMILTON WALKER, Memphis, Tenn., to Miss Anne Marie Byrne of Salem Mass., at Quonset Point R. I. in August.

WILLIAM HARRISON WILLIAMS JR. Charlotte N. C. to Miss Helen Adeline Wheeler of Boston in Portland, Maine, July 3.

THOMAS ANDREW MURRAH III, to Miss Louise Young Workman, both of Charlotte, N. C., August 14.

CHARLES WAIT LLOYD Rochester, N. Y. to Miss Eva Katherine Machen of Belmont Mass. August 14.

WALLACE W. LINDAHL Gainesville Texas to Miss Roberta Alice Collins of Coleridge, Neb., July 7.

CHARLES M. DRUECK JR. Chicago to Miss Alice Lucille Finch of Iroquois, Ill., September 11.

PHILIP MERTZ Dupont Pa. to Miss Rosalie Levkoff of Columbia, S. C., September 19.

ROBERT W. KING to Miss Dorothy Williamson Sisk both of Fayetteville N. C. July 13.

JOHN C. PIERSON to Mrs. Stella Todd Demorest both of New York September 23.

MATHEW GINSBURG Toledo Ohio to Miss Hazel W. Culp of Los Angeles July 31.

Deaths

Ira Solomon Wile ⊕ New York, University of Pennsylvania Department of Medicine, Philadelphia, 1902, formerly lecturer in educational hygiene, New York University and in dietetics and nutrition in the department of dental hygiene at Columbia University, the New School for Social Research, New York University, Hunter College, Columbia University College of Physicians and Surgeons, College of the City of New York and Brooklyn College and for the American Social Hygiene Association, commissioner of education of the city of New York from 1912 to 1918, member of the New York Milk Commission, a founder of the New York school lunch system, Manhattanville Nursery, the National Round Table for Speech Improvement and the Association for Personality Training, of which he was president from 1929 to 1941, a director of the American Birth Control League, member of the advisory council of the Birth Control Clinical Research Bureau and the National Committee on Federal Legislation for Birth Control, member of the American Psychiatric Association, the National Committee for Mental Hygiene, International Committee for Mental Hygiene, American Public Health Association, American Speech Correction Association, Society for the Advancement of Education, American Child Health Association and the American Academy of Political and Social Science, member and in 1932 president of the American Orthopsychiatric Association, specialist certified by the American Board of Psychiatry and Neurology, Inc., associate in pediatrics and formerly assistant clinical pathologist in the dispensary at the Mount Sinai Hospital and clinical pathologist in the children's department of the Vanderbilt Clinic, hospital steward in the Army during the Spanish-American War, author and editor, aged 65, died, October 9, of coronary thrombosis.

Sidney A. Chalfant ⊕ Pittsburgh, University of Pennsylvania Department of Medicine, Philadelphia, 1901, professor of clinical gynecology at the University of Pittsburgh School of Medicine, specialist certified by the American Board of Obstetrics and Gynecology, Inc., past president and secretary and for many years a member of the board of directors of the Allegheny County Medical Society, member of the American Gynecological Society, fellow and past president of the Pittsburgh Academy of Medicine, fellow of the American College of Surgeons, chief of the gynecologic department of Allegheny General Hospital, instrumental in founding and organizing the Woman's Hospital, where he was president of the board of directors and chairman of the hospital staff, a staff member of the Magee Hospital, formerly on the staffs of Columbia and St. Margaret Memorial hospitals, awarded the honorary degree of doctor of science from Geneva College, Beaver College, Pa., aged 68, died, August 31, of pneumonia.

George Herbert Taylor ⊕ Maplewood, N. J., New York Homeopathic Medical College and Hospital, 1904, member of the American Academy of Orthopaedic Surgeons, fellow of the American College of Surgeons, attending orthopedic surgeon and chief of fracture service, Orange Memorial Hospital, attending orthopedic surgeon, East Orange General Hospital, Morristown Memorial Hospital and the Essex County Hospital for Contagious Diseases, Belleville, consulting orthopedic surgeon, Children's Country Home, Westfield, Betty Bacharach Home for Afflicted Children, Longport, Montclair Community Hospital, and the New Jersey Orthopaedic Hospital, Orange, aged 61, died, August 25, of heart disease.

David Yandell Keith ⊕ Louisville, Ky., University of Louisville Medical Department, 1909, member of the American Roentgen Ray Society, American College of Radiology and the American Radium Society, specialist certified by the American Board of Radiology, Inc., on the staffs of the Louisville General, Methodist Deaconess, Kentucky Baptist and the Children's Free hospitals, instructor in surgery at his alma mater from 1909 to 1911, instructor in proctology from 1911 to 1915, instructor in roentgenology from 1916 to 1923, clinical instructor in radiology from 1923 to 1938 and since 1938 clinical associate in radiology, aged 61, died, July 12, of heart disease.

George Ernest Johnson ⊕ Philadelphia, Medico-Chirurgical College of Philadelphia, 1904, assistant professor of laryngology at the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania, specialist certified by the American Board of Otolaryngology, member of the American Academy of Ophthalmology and Otolaryngology, fellow of the American College of Surgeons, chief of the division of communicable diseases for the city department of health from

1934 to 1942, on the visiting staff of the Philadelphia Hospital for Contagious Diseases, served on the staff of St. Agnes Hospital, aged 61, died, August 12, of coronary occlusion.

Henry Nathaniel Sisco ⊕ Baltimore, George Washington University School of Medicine, Washington, D. C., 1909, member of the Washington State Medical Association, served during World War I, formerly associated with the Indian Service, had been health officer of an Indian reservation in Nespelem, Wash., served as medical superintendent of the Chillicothe Indian School Hospital, Chillicothe, Okla., the Clinton (Okla.) Indian Hospital, Salem Indian School Hospital, Chemawa, Ore., and the Washington (D. C.) Sanitarium, Takoma Park, Md., aged 72, died in the United States Marine Hospital, August 4, of retroperitoneal neuroblastoma.

Lewis Weimer Elias ⊕ Asheville, N. C., Columbia University College of Physicians and Surgeons, New York, 1903, member and past president of the state board of medical examiners, past president of the Buncombe County Medical Society, served as secretary-treasurer of the North Carolina Pediatric Society, member of the Southern Medical Association, specialist certified by the American Board of Pediatrics, Inc., pediatrician to the Asheville Mission, Aston Park and Norburn hospitals, Asheville, and the Baltimore (N. C.) Hospital, aged 66, died, August 10, of coronary thrombosis.

John Joseph Finerty, Derby, N. Y., Niagara University Medical Department, Buffalo, 1888, at one time vice president of the Medical Society of the State of Pennsylvania, formerly brigadier general for the Pennsylvania National Guard, served on the staffs of the Charity Eye, Ear and Throat Hospital and the Sisters Hospital, aged 77, died in Buffalo, September 18, of arteriosclerosis.

Adrian William Frankow, West Bend, Wis., Marquette University School of Medicine, Milwaukee, 1934, member of the State Medical Society of Wisconsin, served on the staff of St. Joseph's Hospital, appointed a first lieutenant in the medical corps, Army of the United States, in May 1942 and began extended active duty in June 1942 at Fort George Wright, Wash., a flight surgeon, placed on the inactive list, June 16, 1943, aged 33, died in the Mayo Clinic, Rochester, Minn., August 10, of pulmonary edema.

Oliver Hubbard Gibbs, Waldron, Mich., Eclectic Medical Institute, Cincinnati, 1891, aged 84, died, August 15, of coronary occlusion and general arteriosclerosis.

Louis W. Grosse ⊕ St. Louis, St. Louis University School of Medicine, 1906, served on the staffs of the Lutheran Hospital and Evangelical Deaconess Home and Hospital, aged 58, died, August 20, of heart disease.

George Jacob Gordon, Minneapolis, Jefferson Medical College of Philadelphia, 1900, formerly adjunct professor of therapeutics and instructor in clinical obstetrics at the Minneapolis College of Physicians and Surgeons, the medical department of Hamline University, a founder and for many years director of the Talmud Torah Hebrew School, aged 69, died in St. Mary's Hospital, July 26, of coronary thrombosis.

Andrew Fidelis Gugsell, Ferdinand, Ind., Kentucky School of Medicine, Louisville, 1907, member of the Indiana State Medical Association, at one time served as postmaster at Jasper, served during World War I, aged 67, died in the Stork Hospital, Huntingburg, August 9, of cerebral hemorrhage.

Emmette Marvin Guthrie, Thompson, Ala., Vanderbilt University School of Medicine, Nashville, Tenn., 1905, member of the Medical Association of the State of Alabama, aged 60, died, July 8, of chronic myocarditis, arteriosclerosis and chronic pulmonary tuberculosis.

William Carleton Harris, Cincinnati, Miami Medical College, Cincinnati, 1897, member of the Ohio State Medical Association and the American Academy of Ophthalmology and Otolaryngology, on the staffs of the Deaconess and Jewish hospitals, aged 72, died August 12, of heart blood.

Gustave Hartman ⊕ Lynn, Mass., Jefferson Medical College of Philadelphia, 1904, served during World War I, major in the medical reserve corps of the U. S. Army, not on active duty, aged 66, on the staff of the Union Hospital where he died, August 1, of uremia.

James Francis Hatfield, Rossville, Ind., Medical College of Ohio, Cincinnati, 1897, aged 69, died, August 13, of stroke.

Manley Hewitt Haynes, Menahga, Minn., University of Minnesota Medical School, Minneapolis, 1920, served as health officer and deputy coroner, on the staff of the West Hospital, Wadena, aged 54, died August 8, of pneumonia.

Robert Francis Heatley * Toledo, Ohio, University of Michigan Medical School Ann Arbor, 1923, fellow of the American College of Surgeons, served during World War I member of the staffs of Lucas County and Women's and Children's hospitals, aged 47 secretary of the staff and director of the department of obstetrics and gynecology at the Mercy Hospital where he died, August 3 of Bant's disease

Edmund Bowman Ilyus, Lancaster Pa Jefferson Medical College of Philadelphia, 1882 aged 83 died August 2 of senility

Edward Herman Katterhenry, Indianapolis Gross Medical College, Denver 1897, a captain in the medical department at Camp Custer, Mich, and head of the urology department at the Walter Reed General Hospital Washington D C during World War I aged 69 died in the Veterans Administration Facility, Marion, Ind, August 8, of uremia

E H Kenimer, Bishop, Ga Atlanta Medical College 1897, county physician and chairman of the Selective Service Board on the staff of St Mary's and General hospitals Athens aged 70, died, July 8 of heart disease

Cyrus Kurtz, Paterson, N J University of Maryland School of Medicine, Baltimore, 1902 also a dentist aged 73, died in the Paterson General Hospital, July 23 of cerebral hemorrhage and arteriosclerosis

William T Loftin, Gore, Okla Gate City Medical College Texarkana Ark, 1905 aged 78, died in Tulsa, July 23, of myocarditis

Charles Holder McArthur, Rome Ga, Chicago College of Medicine and Surgery 1917 member of the Medical Association of Georgia on the staff of the McCull Hospital, aged 47 died, August 2, of uremia and lung infection

James Foulhouse McCaleb, Carlisle, Miss, Medical Department of Tulane University of Louisiana New Orleans, 1891 aged 76 died, July 25, of carcinoma of the intestine

William Nelson MacChesney, Evanston Ill Northwestern University Medical School Chicago 1902 at one time on the staffs of the Wesley Memorial Hospital Chicago, and St James Hospital, Chicago Heights aged 67, died in the Illinois Masonic Home, Sullivan, August 18, of Parkinson's disease

Thomas E McGarity, Como, Texas (licensed in Texas under the Act of 1907), member of the State Medical Association of Texas served several terms as mayor of Como and as a member of the board of education of the public schools, aged 70 died July 9, of heart disease

Charles White MacGuire, Toledo Ohio Toledo Medical College, 1898 also a pharmacist, aged 69 died in Columbus July 29 of heart disease

Samuel O Marrs, Chickasha, Okla University of Tennessee Medical Department, Nashville 1893 past president of the Grady County Medical Society, formerly city and county superintendent of public health, at one time secretary of the U S Board of Pension Examiners examiner for the local draft board during World War I, served on the staff of the General Hospital, aged 76, died, August 6 of carcinoma of the liver

Homer Preston Marsh, Syracuse N Y, University of the City of New York Medical Department 1891 formerly coroner of Fulton, Oswego County, N Y, served on the staff of the Crouse-Irving Hospital aged 76 died in St Joseph Hospital, July 29, of coronary thrombosis

George Walworth Mellon, New York University of Pennsylvania School of Medicine, Philadelphia 1913, had been decorated by Crown Prince Alexander of Serbia for his typhus preventive work among the Serbians served in France during World War I formerly consultant to the city board of health and on the staffs of the New York Skin and Cancer Hospital and the New York Post-Graduate Medical School and Hospital aged 53, died, August 7 of heart disease

Frank Waldo Merritt * Gary, Ind, College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois 1905, fellow of the American College of Surgeons for many years chief medical officer of the Carnegie-Illinois Steel Corporation served during World War I on the staff of St Mary's Mercy and Methodist hospitals aged 61 died in his summer home in Miller, August 18 of heart disease

Walter Stevenson Moyer, Sayre Pa Temple University School of Medicine Philadelphia 1910 member of the Medical Society of the State of Pennsylvania aged 70 died July 18

of peritonitis with multiple abscesses due to diverticulitis of the colon

Parley Pratt Musser, Oakland, Calif, College of Physicians and Surgeons Baltimore 1907, at one time bacteriologist for the city of Oakland, aged 69, died, July 20, of cerebral thrombosis

John P Sellman, Washington, Ind College of Physicians and Surgeons, Baltimore, 1896, served as medical examiner for the Baltimore and Ohio Railroad, aged 69, died, August 19 of uremia, pyelitis and cystitis

Charles S Shoaff, Volant, Pa, Keokuk (Iowa) Medical College 1895, aged 77, died in the Jameson Memorial Hospital, New Castle, July 13, of nephritis due to benign hypertrophy of the prostate

Frank Voshell Slaughter, Philadelphia, Hahnemann Medical College and Hospital of Philadelphia, 1899, aged 78, died in the Women's Homeopathic Hospital, August 27, of heart disease

James Augustus Smith * Philadelphia University of Pennsylvania School of Medicine Philadelphia, 1911 served during World War I, on the courtesy staffs of the Kensington Hospital for Women and the Hahnemann Hospital, aged 55, died in the Presbyterian Hospital, August 11, of coronary occlusion

Carl Kennedy Struble, Loveland, Colo, Kansas City University of Physicians and Surgeons, Kansas City, Mo, 1919, aged 69, died in Fremont, Neb, July 30

Merle O Thoreson, South St Paul, Minn, University of Minnesota Medical School, Minneapolis, 1930 member of the Minnesota State Medical Association, member of the medical staff of Swift and Company on the staffs of St Luke's St Joseph's and Children's hospitals, St Paul aged 38 died July 17, of coronary occlusion and myocardial fibrosis

DIED WHILE IN MILITARY SERVICE

John Pierce Beeson * Lieutenant Colonel, M C, U S Army Kansas City, Mo Washington University School of Medicine St Louis, 1905, School for Flight Surgeons and the Air Service Pilot School, 1921, commissioned a captain in the medical corps of the U S Army in 1920, a major in 1929 and a lieutenant colonel in 1937 during World War I served in France as chief of the surgical staff of an evacuation hospital near Verdun had been in command of the station hospital at Fort Hancock N J, and a hospital at Sahna, Kan fellow of the American College of Surgeons aged 59 died in Brownsville Texas, August 1, of coronary occlusion

John Beegan Byrne, Nyack N Y, Columbia University College of Physicians and Surgeons New York 1933, member of the Medical Society of the State of New York diplomate of the National Board of Medical Examiners, at one time resident on the staff of the New York Reconstruction Home, West Haverstraw, captain in the medical corps Army of the United States, aged 36 died in a station hospital at Newfoundland, August 10, of meningitis

Stewart Fulton, Cleveland Rush Medical College Chicago, 1934, formerly resident on the staff of the Fairview Hospital served as medical missionary for the Presbyterian Board of Foreign Missions in India commissioned a first lieutenant in the medical corps Army of the United States May 23 1942 and assigned to the Air Transport Command in New York aged 37 died in the Asiatic area, August 25 of a skull fracture (circumstances unknown)

Lloyd P Gieringer, Toledo Ohio University of Cincinnati College of Medicine 1923 formerly a member of the Mercy Hospital commissioned a lieutenant commander in the medical corps of the U S Naval Reserve Oct 31 1942 stationed at the U S Naval Hospital Newport R I, where he died, August 31 of bronchopneumonia aged 45

John Dendy McBrearty, Williamston S C Medical College of the State of South Carolina Charleston 1938 commissioned a first lieutenant in the medical reserve corps of the U S Army, Sept 29 1941 and later a captain an aviation medical examiner attached to the anti-submarine command aged 29 died in an airplane accident near Earlton N Y July 22

Correspondence

CENSORSHIP OF MEDICAL PERIODICALS

To the Editor —In THE JOURNAL of May 8, which has just now come to hand, I have read with interest and sympathy the communication of Dr Houssay protesting against the censorship of medical articles. We in India also have been sufferers in this respect. Although, as far as I know, no issue of THE JOURNAL coming to India has until now been censored, since the nonarrival of certain numbers has been ascribed naturally to enemy action, nevertheless one number of the *American Journal of the Medical Sciences* did arrive badly blotted and cut up. Also the April 1943 number of the *Surgical Clinics of North America* has failed entirely to arrive and its publishers have written to say that the fault is censorship in this case. From advertisements appearing elsewhere, I understand that the April issue of the *Surgical Clinics of North America* had a symposium on war surgery. It can only be concluded that American censorship is keeping information from this country which might be of value in India's war effort. It is difficult to understand an attitude that will interfere with the dissemination of medical knowledge under any circumstances. Still less understandable is the keeping of such information from nations which are America's allies in the present struggle.

"CONTACT, CONTACT-INFECTIVE AND INFECTIVE-ALLERGIC DERMATITIS"

To the Editor —I should like to make a few comments on the article by Drs Stokes, Lee and Johnson entitled "Contact, Contact-Infective and Infective-Allergic Dermatitis" appearing in THE JOURNAL, September 25.

A bilateral chronic and recurrent dermatitis of the hands of a physician should be considered to be due to a rubber glove sensitivity until proved otherwise. Dr Stokes neglected to point out an occasionally important factor—that of localized sensitivity. Localized or regional epidermal sensitivity has long been recognized by dermatologists. An example of this is nail polish dermatitis of the eyelids and face, where patch tests of nail polish may be negative on the arms or back yet be strongly positive when applied to the forehead or side of the neck. In the same manner patch tests of a suspected rubber glove actually causing a dermatitis of the hands may yield a negative test when performed on the back or arm. For this reason rubber glove dermatitis of the hands has been missed in some physicians and the dermatitis considered to be soap and water dermatitis or an eczematoid dermatophytid. The latter may be the case especially when a coexisting dermatitis of the feet due to rubber or rubber cement of the shoes is considered to be due to dermatophytosis.

I wish to recommend strongly that every physician with a suspected rubber glove dermatitis be tested on the hands. This may be done by patch tests, but I have found the simplest method to be that of wearing a cotton glove with a small hole cut out of the back under the rubber glove. If the patient is sensitive, a small patch of dermatitis corresponding to the hole in the back of the cotton glove will appear.

The wearing of Neoprene or rubber gloves to which the patient is not sensitive may not end his troubles, for he may come into contact with innumerable other rubber articles. I

have one patient, a woman, who, while working in the processing department of a synthetic rubber plant, became sensitive to the synthetic rubber with a resulting dermatitis of the hands and forearms. After recovery she obtained work as a secretary. A short time thereafter a troublesome dermatitis appeared on her hands. Patch tests of a rubber typewriter eraser, rubber typewriter key pads, a rubber covered adjustment knob on the typewriter, a rubber finger protector and the rubber telephone receiver all gave strongly positive reactions.

DOCTORS AS "SOFT TOUCH" FOR NARCOTIC ADDICTS

To the Editor —Because of the shortage of narcotic drugs in the illicit traffic, drug addicts are calling on members of the medical profession looking for a "soft touch." This is the addict's term for a doctor who will write a narcotic prescription after listening to a plausible tale. Hundreds of such cases are coming to our attention.

A drug addict goes into a doctor's office and simulates a bad cough. He tells the doctor that the only thing that will help him is a drug, the name of which he has on a slip of paper. He shows the doctor this slip of paper, on which the word Dilaudid is written. He takes a chance that the doctor is unaware of the fact that this drug is a derivative of morphine. It is surprising how many doctors follow the addict's suggestion and write a prescription for Dilaudid.

In another racket the physician is imposed on in a rather unusual manner and generally writes morphine prescriptions for quantities ranging from thirty to eighty $\frac{1}{4}$ gram tablets. The addict calls on a physician and says his wife is in the care of a nurse and enroute by train to join him, that his wife is in a very serious physical condition, necessitating the use of morphine. He says that the doctor has been highly recommended and that he wants him to take care of his wife on her arrival, place her in a hospital and perform an operation if necessary. The addict offers a retainer. He then alleges that his wife has just stopped off in a nearby city and is unable to proceed by train until a supply of morphine is obtained, that the nurse telephoned him that his wife's supply is exhausted. The physician writes a prescription for morphine, which the addict claims he will send to his wife by air mail. In some cases the doctor has been taken in by this story to the extent that he has retained a room in a hospital for a week until he realizes that he has been victimized.

When addicts find a notice of a doctor's death in an obituary column they sometimes call on the bereaved widow on the day following the death alleging that they are narcotic inspectors and have come to take charge of the doctor's morphine stock.

Pharmacists are being deluged with forged narcotic prescriptions. Blank pads are being stolen from doctors' desks by addicts. Several times we have referred to numerous thefts of physicians' bags containing narcotics. A doctor's bag left in a parked automobile near a hospital is invariably stolen by a drug addict.

Physicians are being imposed on with increased frequency. I know they are extremely busy during this emergency. They should be warned to be on guard when a stranger tries to induce them to write a narcotic prescription. Many of the drug addicts today tell us that they are obtaining narcotics to satisfy their craving by going to various physicians and simulating some serious physical ailment.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Legality of the Corporate Practice of Medicine—The Bartron Clinic was organized in 1929 as a corporation for profit and, in general, it operated in South Dakota a hospital and clinic and supplied medical and surgical services and necessary drugs to persons availing themselves of its services. In carrying on its activities it acted, to all practical purposes, only through licensed physicians and surgeons and nurses in its employ. Each employee seemed to have confined his or her activities to fields in which he or she was licensed to practice. The corporation had 750 shares of capital stock, all but 28 of which were owned by duly licensed physicians connected with the activities of the corporation. Admittedly the corporation was not licensed to practice medicine and surgery nor to operate a pharmacy in South Dakota. In 1933 and in succeeding years until 1938, when it ceased to do business, the corporation contracted on an annual basis with Codington County, S D, to furnish necessary hospitalization medical and hospital services and medicine to the poor of the county for whom it was the duty of the county to provide. Subsequent to the time when the corporation ceased to do business three cases involving the contracts between the corporation and the county were instituted. In one case a claim was filed with the county commissioners for compensation for medicines supplied to county indigents. Another case originated as a claim for the recovery of compensation for medical and surgical services rendered by the corporation. The third case originated as an action by the county to recover monies paid from 1933 on to the corporation for medical and surgical services and medicines furnished to the county indigents by the corporation. The judgments in the lower court in these cases were adverse to the corporation. On appeal, the Supreme Court of South Dakota disposed in a single opinion of the issues presented in the 3 cases.

To sustain the judgments of the trial court the county contended, first, that under the medical practice act of South Dakota the corporate practice of medicine was illegal and a corporation could neither recover nor retain compensation for acts in violation of that act. In the exercise of the police powers of the state, said the Supreme Court, the legislature can prohibit corporations from engaging in the business of supplying for gain the services of licensed physicians. The question here is whether or not the South Dakota medical practice act evidences an intent on the part of the legislature to do so. Section 7717, Compiled Laws, 1919 (a section of the medical practice act), provides a penalty for 'any person who shall practice medicine in this state without having obtained a license. Assigning to the word 'practice' the broad significance of common usage, and applying also the statutory rule that "person" also includes a corporation, the corporation, functioning through licensed physician employees acting within the scope of their authorized powers has practiced medicine and surgery in apparent violation of the act unless a different legislative intent is plainly revealed elsewhere in the act. The most cursory analysis of the medical practice act reveals that it was motivated by a purpose to bring a high standard of character and competence to the diagnosis and treatment of human ailments and to prevent the quack and the unfit from ministering unto the ills of mankind. To accomplish these purposes a system of licensure was set up based on personal qualifications including age character schooling training and professional conduct and a penal provision was added to the act to deter the unfit from treating patients. It will be further noted that throughout the act the legislature has dealt with the functions of natural persons and has ignored their legal relationships. Although the act by the power it grants in sections
